SYNTHESIS OF OXA-BRIDGED 7- AND 8-MEMBERED RINGS VIA INDIUM-MEDIATED ANNULATION OF 1,4- and 1,5-DICARBONYL COMPOUNDS WITH 3-iodo-2-[(trimethylsilyl)methyl]propene

Abstract – A variety of 1,4- and 1,5-dicarbonyl compounds undergo reaction with 3-iodo-2-[(trimethylsilyl)methyl]propene in the presence of indium metal in aqueous media to produce oxa-bridged 7- and 8-membered rings in good yields. The reaction mechanism likely involves intermolecular indium allylation of one carbonyl of the substrate, followed by indium-halide promoted intramolecular allylsilane cyclization. This procedure offers an environmentally friendly alternative to the analogous tin-mediated annulation process.

The wide occurrence of seven and eight-membered carbocycles in natural products has stimulated numerous efforts on the part of synthetic chemists to develop a general method for the synthesis of medium rings akin to the Diels-Alder reaction employed for formation of six-membered rings. The development of [m+n] annulation reactions, wherein a carbocycle is generated from two acyclic precursors in a single synthetic operation, remains an important focus of synthetic effort. Molander has reported a successful [3+4] and [3+5] annulation approach to seven and eight membered rings involving combination of dicarbonyl compounds with 3-iodo-2-[(trimethylsilyl)methyl]propene (1) as a trimethylenemethane dianion synthon. The process is promoted by SnF₂, which serves to generate allylstannane (2) from 1 in situ (Scheme 1). Carbonyl allylation is then followed by hemiacetal formation and allylsilane cyclization, promoted by the presence of both Sn⁴⁺ and fluoride ions, to provide the oxa-bridged carbocycle in high yields. One undesirable aspect of this procedure is the necessity for use of stoichiometric amounts of a toxic tin reagent.
The indium-mediated allylation of aldehydes and ketones in aqueous media is a powerful and stereoselective carbon-carbon bond-forming reaction that has been applied to the synthesis of a variety of complex natural products. In view of the environmentally benign characteristics of indium metal, we decided to explore the possibility of performing the above \([m+n]\) annulation process in aqueous solvent systems using indium as a mediator.

Combination of equimolar amounts of 1, 5 phthalic dicarboxaldehyde (3a), and indium powder in DMF at room temperature for 16 hours gave rise to a 4:1 mixture of hemiacetal (4) (as a mixture of diasteromers) and methylene cycloheptane (5) (Scheme 2). Stirring the reaction mixture for an extended time period gave no further increase in the yield of 5. Treatment of the isolated, crude reaction products with a catalytic amount of BiCl₃ in CH₂Cl₂ at room temperature for 3 hours gave essentially complete conversion to 5 in 60% overall yield.

Although an alternative path to a seven-membered oxa-bridged carbocycle had been achieved, we desired a one-pot process that could furnish high yields of annulation products in the absence of halogenated...
solvents. Gratifyingly, it was found that stirring equimolar amounts of 1, phthalic dicarboxaldehyde and indium powder in 4:1 H₂O:i-PrOH at room temperature for 36 hours gave rise to carbocycle (5) exclusively in 85% yield (Scheme 2). Combination of 1 with diketone (3b) (Table 1, entry 2) similarly furnished 5b in 60% yield. Substrates (3c)⁹ and (3d)¹⁰, with increased steric hindrance at the carbonyl groups and decreased solubility in the reaction medium, gave lower percent conversions (~15%) even after 48 hours of stirring. However, by simply increasing the proportion of isopropanol cosolvent (to 3:1 H₂O: i-PrOH), the yield of oxa-bridged cycloheptanes (5c) and (5d) increased, with optimal conversions (40% and 35%, respectively) achieved between 36 and 48 hours at room temperature. It is noteworthy that starting diketones (3c) and (3d) could be recovered in ~50% yield from these reactions.

Table 1. [3+4] annulation reactions of 1 with 1,4-dicarbonyl compounds in the presence of indium metal

We next investigated [3+5] annulation reactions between 1 and 1,5-dicarbonyl compounds in the presence of indium metal. Treatment of 1,5-diphenylpentane-1,5-dione (6a) with one equivalent each of 1 and indium metal in 4:1 H₂O: i-PrOH gave, after 48 hours stirring, a 79% yield of the eight-membered oxa-bridged carbocycle (7a) (Table 2). Similarly, diones (6b)¹¹ and (6c)¹² furnished carbocycles (7b) and (7c) in 82 and 65% yields, respectively, each as a mixture of diastereomers. Keto-aldehyde (6d)¹³ also underwent smooth annulation with 1 in the presence of indium metal to provide 7d¹⁴ in 60% yield. Subjection of glutaraldehyde (7e) to the reaction conditions, however, gave rise to a complex mixture of
products with only trace amounts of cyclized material; Molander has also observed low yields for [m+n] annulations employing enolizable aldehydes.3

* Reaction conditions: equimolar mounts of 1 + 6 + In(0) in 4:1 H2O:i-PrOH, rt, 48 h. Reaction performed in 3:1 H2O:i-PrOH. Isolated as a 3:1 mixture of diastereomers. Isolated as a 1:1 mixture of diastereomers. Isolated as a 6.5:1 mixture of diastereomers. Refers to yields of chromatographically purified products.

Finally, we combined cyclohexenyl iodide (8) with 3a under our standard reaction conditions; after 48 hours, tricycle (9) was isolated in 55% yield as a 15:1 mixture of diastereomers (Scheme 3). This experiment demonstrates that more complex (silyl)allyl iodides may also be employed in aqueous [m+n] annulations.

Paralleling the SnF₂-promoted process, the mechanism of this reaction likely involves \textit{in situ} allylindium generation (furnishing \textbf{A}, scheme 4) followed by intermolecular carbonyl allylation, providing diastereomeric hemiacetals \textbf{B}; when the reactions are stopped after 5 hours, this is the main product obtained. The indium (I) and/or indium (III) halide salts produced in the initial steps then function in the capacity of a Lewis acid by slowly catalyzing an intramolecular allylsilane cyclization reaction (\textit{via} structures \textbf{C} or \textbf{D}), furnishing product \textbf{E}. The indium salts also facilitate enolization of aldehydes such as \textbf{6e}, leading to numerous aldol-type side reactions for these substrates over the lengthy reaction period. Furthermore, it is possible that when the reaction is performed in DMF, the cyclization step is inhibited because the Lewis acidic indium species preferentially coordinate the electron-rich formamide carbonyl oxygen of the solvent.

In summary, we have established that [m+n]-type annihilation reactions can be carried out in aqueous media when indium metal is employed as a promoter of reactions between 2-[(trimethylsilyl)alkyl]allyl iodosides and 1,4 or 1,5-dicarbonyl compounds.\textsuperscript{17,18} We anticipate that this environmentally benign methodology for constructing seven and eight-membered carbocycles may find broad applicability in natural products synthesis.

\textbf{ACKNOWLEDGEMENTS}

This paper is dedicated with great respect to Professor Yoshito Kishi on the occasion of his 70\textsuperscript{th} birthday. We also thank the ACS Petroleum Research Fund (No. PRF 45277-B1) and Research Corporation (No. CC6343) for their generous support of our research program. We also thank Mr. Jesse Brister for initial preparations of compound \textbf{5a} in water.
REFERENCES

5. Compound (1) was prepared (MsCl, Et₃N, THF; NaI, acetone) from the corresponding allylic alcohol: B. M. Trost, D. M. T. Chan, and N. Nanninga, Org. Synth., 1984, 62, 58.

7. Silica gel chromatography of the isolated, crude reaction products (a 4:1 mixture of 4 and 5) also led to the isolation of 5 in ~60% overall yield, presumably because of acid-catalyzed dehydration/intramolecular cyclization of 4 occurring during chromatography.

17. General Procedure: to a 10 mL round-bottom flask equipped with magnetic stirbar was added the dicarbonyl compound (3 or 6, 1.0 mmol). A 4:1 H₂O:i-PrOH solution (0.4 mL) was added and
stirred until a monophasic solution was obtained; if the dicarbonyl substrate did not completely
dissolve, additional i-PrOH was added dropwise to effect a greater degree of homogeneity (~3:1
H₂O:i-PrOH). Then indium powder (1.0 mmol) was added in a single portion. To the stirring
solution was added 3-iodo-2-[(trimethylsilyl)methyl]propene (1, 1.0 mmol), and the reaction flask
was covered with a septum and shielded from light with aluminum foil. After stirring for 48 hours,
the mixture was diluted with ether (2.0 mL) and washed with brine (2 x 2.0 mL). The organic extract
was dried over sodium sulfate, filtered, and concentrated in vacuo. Purification of the residue by
flash chromatography (SiO₂, 98:2 hexanes:ether as eluant) afforded pure oxabicyclic products (5, 7,
or 9).
