1. INTRODUCTION

In a recent proposal, the term "meso-ionic" has been confined to five-membered heterocycles "which cannot be represented satisfactorily by any one covalent or polar structure and possess a sextet of electrons in association with the five atoms comprising the ring". We and others prefer a broader definition of this term - i.e. one which covers six-membered heterocycles as well, and it seems appropriate to include mesomeric betaine derivatives of heteropentalenes and even squaraines. In this review, only those six-membered mesoionic heterocycles will be dealt with which can be derived formally from the m-quinodimethane dianion (Chap. 2.).

2. DEVELOPMENT OF POSSIBLE SYSTEMS NOMENCLATURE

If the atoms 4, 5, 6 or 2, 5, and 7, 8 in the m-quinodimethane dianion (Scheme 1)
are substituted by N-, O, or S, respectively, three types of monocyclic mesoionic six-membered heterocycles will be obtained (A, B, C) which can be considered as 1,3- (A,C) or 1,4-dipolar (B) systems. Further introduction of appropriate heteroatoms (e.g. -N in position 4 of A, in position 2 and/or 5 of B) enlarges the number of possible heterocycles considerably; the extension of these general types, including selenium\textsuperscript{10}, provides the possibility of even more systems (Chap. 4.1.4). The connection of atoms C2 and N1, N1 and O7, O7 and C5, or C5 and O8, respectively, with homo- and/or heterocyclic 4\pi-rings leads to bi- and polycyclic systems (Scheme 2). The extension of this development is straightforward (B5 in Scheme 2), but since examples of these types of compounds are rare, this matter will not be further dealt with.

\textbf{Examples: (Type B2 unknown)}

\textbf{Scheme 2}
As in the case of five-membered mesoionic heterocycles, their six-membered analogues can be described only by several formulas involving positive and negative charges at various positions (Scheme 3, e.g. a–c); there may be arguments favouring one of these symbols, but it should be recognized that the electron distribution differs from one system to the other and that a "neutral" formulation (d, e) is to be preferred at the moment. Formula d implies a partial double bond character of the C=O-bonds; however, X-ray data do not substantiate this view (Chap. 3). With regard to these results, we advocate a description in which the carbonyl groups (or their equivalents) are explicitly written and which does not anticipate an experimentally unexplored charge distribution. In the opinion of one of these authors (W.F.), formula e serves quite well for this purpose, differing only marginally from a description (f) given by Coburn \(^{11}\) and Glennon \(^{12}\).

The systematic naming of mesoionic compounds is not standardized. In Chemical Abstracts

(1) : 5,6-Dihydro-4,6-dioxo-4H-1,3-diazinium hydroxide, inner salt.
(2) : Anhydro-4-hydroxy-6H-6-oxo-1,3-diazinium hydroxide.
(3) : 6H-6-Oxo-1,3-diazin-1-ium-4-olate.
(4) : Mesoionic 4,6-Dioxo-1,3-diazine.

Naming of Mesoionic Six-Membered Heterocycles

SCHEME 4
nomenclature (I), (Scheme 4) is used. Still another systematic description is in use, especially in the German literature ((3)): the mesoionic compound is treated as an intramolecular salt of an alcohol ("olat") with a cationic system ("ium" as suffix). However, these designations are somewhat cumbersome; therefore as a short-hand notation it seems convenient to refer to the mesoionic systems in terms of the parent heterocycle together with the adjective "mesoionic" (Chap. 4).

3. THEORETICAL AND STRUCTURAL INVESTIGATIONS

Even simple HMO calculations reveal that there is a remarkable stabilisation to be found from the m-quinodimethane dianion (I) to mesoionic heterocycles of type A, B, and C (Scheme 5). HMO-, together with CNDO/2\textsuperscript{14}-data\textsuperscript{15} of the mesoionic systems, is shown in Table 1. The HMO eigenvalues of the mesoionic systems range from 9.431 to 10.998, indicating a high degree of stabilisation.

\[ E_\pi[B]^a = 9.431 \quad 11.054 \quad 11.297 \quad 10.998 \]

\[ a: \text{Net } \pi\text{-bonding energy}^{13}. \]

HMO eigenvalues; heteroatom parameters:
\[ \delta\chi_N = 1.5\beta, \delta\chi_O = 1.0\beta, \delta\beta_{C-N} = 0.8\beta, \delta\beta_{C-O} = 1.0\beta, \delta\beta_{N-N} = 0.6\beta. \]

*Scheme 5*
4,6-dioxo-1,3-diazines B, 2, and 3, show - as expected - a reduced \( \pi \)-electron density at C2 and an enhanced \( \pi \)-electron density at C5. Interestingly, in 2 the heterocyclic ring acts as an electron acceptor, whereas in 3 it acts as an electron donor. These results are also obtained within the Hückel scheme. Both the Hückel and the CNDO/2 method predict a 2-phenyl-substituted 1,3-diazine (2) slightly more stable than the 5-substituted derivative (3). An important conclusion concerning the structures of compound B, as well as mesoionic 4,6-dioxo-1,3-oxazines, can be drawn from these calculations. As shown in Table 1, the bond order between N3 and C4 is very small - even lower than the corresponding value in the m-quinodimethane dianion.

TABLE 1
Similar values are obtained for the bicyclic derivatives $B_1$, $B_2$, and $B_3$ with the variable-electronegativity PPP-SCF procedure (VESCF-M0)\textsuperscript{17a} (Scheme 6). One would expect an unusual long bond length between these atoms; these results have been confirmed recently by X-ray structure determinations. Up to now only two structure determinations of compounds of type $B$ have been described. Both the mesolonic 1,2,3,5-tetraphenyl-4,6-dioxo-1,3-diazine (4) and the 2-ferrocenyl-1,4-diphenyl-4,6-dioxo-1,3-oxazine (5) show extraordinarily long C-N- and C-O-distances (Scheme 7). These

findings have also been discussed in terms of Dähne's concept of two coupled poly-
methines. It may be remarked that compounds \(\text{4} \) and \(\text{5} \) show C=O-bond lengths, which are in the range of the values for normal carbonyl groups; a partial double bond character which is suggested by a mesomeric form \(\text{4} \) (Scheme 3) could not be sub-
stantiated.

4. SYNTHESES AND SPECTROSCOPIC PROPERTIES

4.1 1,4 - DIPOLAR SYSTEMS

4.1.1 4,6-Dioxo-1,3-diazines

Monocyclic Compounds. Syntheses

The parent compound of mesoionic 4,6-dioxo-1,3-diazine is the 4,6-dihydroxypyrimidine (6). Katritzky and coworkers have demonstrated by UV, IR, \(^1\)H-NMR, and \(pK_a\) measure-
ments that 6 exists in water predominantly as mesoion \(\text{6}^{-}\), together with a substantial amount of 6-hydroxypyrimidine-4(3H)-one (8). 4-Hydroxy-6-mercaptopyrimidine (9) may exist also in various tautomeric forms. Brown and Tate have advanced arguments
for the oxo-thiono form (11) in water and ethanol, possibly with small amounts of 10 and 12; however, the mesionic tautomer 13 which has not been taken in account by these authors has recently been considered as the most likely structure. It is noteworthy that 6-hydroxy-4-pyrimidones may undergo inter- and intramolecular \([\pi_4+\pi_2]\)-cycloaddition reactions, possibly via the 1,4-dipolar form (15). In some instances the primary adducts (16, 21) have been detected. However, with bulky sub-
stituents in position 2, 3, and 5 of the hydroxyprymidone (14b) no cycloaddition with DMAD \(^{29}\) could be observed and the addition products 18, 19, and 20 are obtained. \(^{28}\) True monocyclic derivatives of 7 have been described for the first time by M. Prys-tas. \(^{30,31}\) The already reported \(^{33}\) treatment of 4,6-dimethoxyprymidinone (23) with methyl iodide yields the known compound 24 accompanied by its metholiodide (25) and the high melting (mp 276-278°C (nitromethane)) dimeric mesionic 4,6-dioxo-1,3-diazine 26. By heating the reaction mixture in a sealed vessel at temperatures exceeding 70°C, an almost quantitative yield of 26 is obtained. Fission of 25 with hydrogen bromide in acetic acid, which has been reported by Soviet authors \(^{34}\) to give the monomeric form of 26, also leads to 26 (90% yield); a short heating of 25 (220°C, 5 min.) produces 26 in 77% yield.

The action of hydrogen bromide in acetic acid on 27 yields 28 (which may exist in solution as 30) and 29. \(^{30}\) In the same paper, the reaction of 4,6-dimethoxy-5-phenylpyrimidine (31) with methyl iodide is described to give 32. Later on \(^{35}\), the thermal

\]

Rearrangements of 4,6-dimethoxy-5-nitopyrimidines (33) are reported to yield 34 and 35. Obviously, compounds 33 are intermediates; on heating to 200°C they give the final products (34). The mechanism of these reactions is not yet clear; a double 1,3-dialkyl O-N migration via a radical mechanism is suggested. The proposed structures 34 and 35 rest on spectral data (Scheme 8) and chemical reactions. Compound 26 is very readily cleaved by alkali under the formation of malonic acid N,N'-dimethylamide. Furthermore 26 and 32 are hydrogenated (Pd/C) to give 36a, b; the hydrogenation of 26 proceeds sluggishly because of a very slow attainment of
an equilibrium of 26 and its mesolonic monomer. Only this monomer then undergoes the hydrogenation

The first general syntheses of mono- and bicyclic mesolonic 4,6-dioxo-1,3-diazines were published almost simultaneously by two research groups 36, 37. The reaction of \( \text{N,N}' \)-disubstituted amidines 38 (37) with reactive malonic esters as malonic acid bis-(2,4,6-trichlorophenyl)esters at 160°C gives 39 in good to excellent yields (trichlorophenyl malonate procedure) 37. Bicyclic derivatives (41b–g) are obtained in the same way from N-substituted 2-aminopyridines. Refluxing anisole (bp. 154°C) has proved to be a suitable solvent for this reaction 40. Longer reaction times and enhanced temperatures should be avoided since liberated trichlorophenol specifically catalyzes a rearrangement of the mesoions 39 41 (See Chap. 5.5). Both compounds 41a and 41b were

prepared from the corresponding N-substituted 2-aminopyridine with carbon suboxide at room temperature in the absence (41a) or presence (41b) of a catalytic amount of AlCl₃. (For further details on bi- and polycyclic derivatives, see below.) This reaction has also been used for the preparation of monocyclic mesoions.
bearing no substituent at C5 (42a-d, 42e (from an oxime ether), 42f-k (from isothiouras), 42b, 42l (from isoureas)).

The reactivity of the bielectrophilic malonic acid derivative can be enhanced by the use of bis(pentachlorophenyl)esters. Thus 39a is prepared from N,N'-diphenylbenzenecarboximidamide and malonic acid bis(pentachlorophenyl)ester in acetone with two equivalents of triethylamine at room temperature. However, the yields obtained by this procedure amount to about 50% of the thermal condensation reaction only.

The extension to bicyclic "malonyl-α-amino-pyridines" has been reported.

In a further synthesis of monocyclic compounds of type 39 mesoionic 4,6-dioxo-1,3-thiazines (43) are used as starting materials, which in turn are available from N-monosubstituted thioamides and reactive malonic acid derivatives (malonic acid dichlorides, substituted chlorocarbonylketenes; see Chap. 4.1.2). When the compounds 43 are heated together with aryl isocyanates, the mesoionic 4,6-dioxo-1,3-diazines 45 are obtained in 75-83% yield; an intermediate of type 44 is possibly involved which on loss of COS gives the final products. This synthetic sequence may be preferred over the trichlorophenyl malonate procedure described above in those cases where N-monosubstituted thioamides are readily available.

In the same way, mesoionic 4,6-dioxo-1,3-oxazines (47) (e.g. 46) may react with aryl isocyanates to produce 4,6-dioxo-1,3-diazines (e.g. 47).
An unusual route to mesoionic 4,6-dioxo-1,3-diazines was described by H.W. Moore and coworkers. When 4-azido-2-pyrrolinones (48) were thermolyzed in refluxing benzene or when one equivalent each of chlorocyanoketene (51) and the formimidates 52 were subjected to the same reaction conditions, in addition to the major 6-lactams (50) the 4,6-dioxo-1,3-diazines 54 were isolated (5-20%). Yields, however, can be improved by carrying out the thermolysis in the presence of an excess of the formimidates 52. A mechanism which accommodates to the observed products is given in Scheme 9.

Mesoionic 4-oxo-6-thiono-1,3-diazine (13) is the parent compound for unsymmetrical systems of this type. Only a few monocyclic - and polycyclic (see below) - derivatives have been described hitherto. On heating with phenyl isothiocyanate, the meso-
Ionic oxazine 46 yields 55 with loss of CO₂. In a comparable reaction, 56 reacts with the same heterocumulene to yield 57. This seems to be the first example of the conversion of a five-membered mesoionic ring system into a six-membered mesoionic ring system.

Monocyclic Compounds. Spectral Data
Monocyclic mesoionic 4,6-dioxo-1,3-diazines are colorless (Table 2, compounds a-d) or slightly yellow to yellow-orange (compound c, d, e-g) well-crystallized high melting solids. In their IR spectra, they exhibit a very strong carbonyl band at 1650 to 1670 cm⁻¹ normally associated with a shoulder or a second absorption at slightly higher wave numbers. The UV spectra show a long wavelength absorption at approximately 350 nm (ε:10⁴) with a second maximum near 260 nm. The ¹H-NMR spectra show

the C2-proton at very low field (comp. 26,32) in the pyrimidine region.\textsuperscript{56} The N-CH\textsubscript{2} group appears in the amide area with a small downfield shift (\textsuperscript{32}: \(\delta (\text{CH}_2) = 3.16\) ppm).\textsuperscript{50} H5 suffers from a remarkable downfield shift compared with CH\textsubscript{2}-groups flanked by two carbonyl moieties; whether these values are the result of two opposite effects—a ring current effect and a highfield shift induced by a partial negative charge at C5— is open to question. In trifluoroacetic acid there occurs protonation on the exocyclic oxygen atom; this is accompanied by a considerable downfield shift of C5-H and C2-CH\textsubscript{3} (\(\delta = 1.5\) and 0.5 ppm, respectively, for compounds a-d of Table 2).\textsuperscript{44} Only a few \textsuperscript{13}C-NMR data have been reported. Two representative examples are shown.

\textsuperscript{13}C-NMR Data of Mesoionic 4,6-Dioxo-1,3-diazines.

\textbf{SCHEME 10}

in Scheme 10. Attempts have been made to relate charge densities (calculated by a MINDO method) and \textsuperscript{13}C-NMR chemical shifts.\textsuperscript{57} It is interesting to note that there seems to be no significant delocalisation, neither of a positive or of a negative charge, into phenyl-substituted derivatives.\textsuperscript{57} The charge distribution in monocyclic and bicyclic mesoionic 4,6-dioxo-1,3-diazines (and a bicyclic 4,6-dioxo-1,3,5-triazine; see Chap. 4.1.6) has been investigated by ESCA spectroscopy.\textsuperscript{58} In the former two types of compounds the positive charge is distributed among both nitrogen atoms; the N-1s bond energies are found to be in the region of 401.1–401.5 eV.\textsuperscript{59}

\textbf{BI- and Polycyclic Compounds. Syntheses}

2-Aminopyridine (58) reacts with diethyl malonate to give a compound named "malonyl-\(a\)-aminopyridine".\textsuperscript{60,61} which has been formulated by Tschitschibabin in the dioxo-form (59). As Snyder and Robinson have pointed out, the physical properties (e.g. high mp 301–302°C,\textsuperscript{62} low solubility in non-polar solvents) were in contrast to this for-
These authors favored hydroxy-oxo-structures. Katritzky and Waring have indicated that only the mesionic formulation (60) is in accordance with the physical properties of "malonyl-α-aminopyridine". Alkylation of "malonyl-α-aminopyridine" with alkyl halogenides yields - in contrast with previous investigations - O- and N-alkylated products. C-Alkylation seems to have been observed in only one case, i.e. where the reaction of 60 with benzyl bromide (DMF/K₂CO₃) yields - besides 61d/62d (40% and 20%, resp.) - 5% of a mixture

Scheme 11
which consists of 64b and 65b (Scheme 12). These compounds result from a primary
C-alkylation. The methylation with methyl iodide which has been reported to give
62a yields 61a also. A mixture of 61a (20%) and 62a (50%) is also obtained from
60 and diazomethane (in dioxane/methanol). The alkylation of 63 yields O- and N-
products also (64, 65).

IR, UV, and 1H-NMR spectra of mesionic pyrido[1,2-a]pyrimidine-2,4-diones have been
investigated extensively. Some representative examples are collected in Table 3. The IR spectra show at least two bands in the C=O-region. The UV spectra
exhibit an absorption at longer wavelengths with an extinction coefficient of approx.
4 × 10³, depending somewhat on the substitution at N1 and C3. (For details with figures
of IR and UV spectra, see loc.cit.68b) The 1H-NMR spectra are similar with those
of the monocyclic compounds (see Table 2) in respect of the C3-proton and the N-
alkyl groups.

The alkylation reactions have been extended to various substituted mesionic pyrido-
[1,2-a]pyrimidine-2,4-diones and to 67, which is obtained by condensing aminopyra-
zine (66) with ethyl phenyl malonate. Physical properties of 67 indicate that it
exists predominantly as mesocion. It differs chemically from "malonyl-a-aminopyridine"
in such a way as to fail to produce a chloride when treated with POCl₃; base-catalyzed
alkylation resulted only in 0-alkylated products.

this latter compound was obtained by dehydrogenation of perhydropyrido[1,2-a]pyrimidine-2,4-dione (70).

As already mentioned in the subsection "Monocyclic Compounds", mesoionic systems of type 62 (and 65) can be conveniently prepared from the corresponding N-substituted aminopyridine with a bielectrophilic malonic acid derivative (C\textsubscript{6}O\textsubscript{2}, substituted malonyl dichlorides, substituted chlorocarbonylketenes, alkyl malonates, bis(2,4,6-trichlorophenyl) malonic esters). This procedure has been extended to various bi- and polycyclic systems which contain an amidine moiety. Mesoionic pyrimido[1,2-b]-pyridazine-2,4-diones (72) were prepared by the condensation of 3-(N-substituted amino)pyridazines with bis(2,4,6-trichlorophenyl) methylmalonate at 160° C under a slow stream of nitrogen until a clear melt was obtained (7-10 min.); purification was conveniently achieved by recrystallization from acetonitrile\textsuperscript{72}. The chloro group could be displaced to give 72 with substituents such as methoxy, anilino, morpholino,
N-methylpiperazyl, and hydrogen. Some of these compounds exhibited evidence of antimicrobial activity\textsuperscript{72a}. The mesoionic 2,4-dioxopyrimido[1,2-a]pyrimidine (74) was prepared from 4,6-dimethyl-2-methylaminopyrimidine (73) and carbon suboxide\textsuperscript{73}. A very interesting system (75) has been described which can formally be considered as a dibenzo analogue of a 12π-system (B5, Scheme 2)\textsuperscript{37}. These compounds can be prepared in the usual manner from indophenazine using the trichlorophenyl malonate procedure; they form deep green (75a) or deep red (75b) high melting solids which seem to show a pronounced solvatochromic behavior. Further compounds of this type have not been described as yet.

The connection of mesoionic 4,6-dioxo-1,3-diazines with a five-membered heterocyclic ring leads to a class of compounds which have been called "mesoionic purinone analogues" (B1: mesoionic xanthines; B2: mesoionic purin-2-ones; B3: mesoionic hypoxanthines)\textsuperscript{17}. In this review, these bicyclic systems (the extension to polycyclic analogues is straightforward) will be treated as members of mesoionic six-membered heterocycles of type B (Scheme 1). Only a few examples have been described up until now.
Mesoionic purinone analogues 17

Mesionic thiazolo[3,2-a]pyrimidine-5,7-diones (76) have been prepared from N-substituted 2-amino-1,3-thiazoles via the trichlorophenyl malonate route 11,12 or with (chlorocarbonyl)phenylketene 74. They form colorless to slightly yellow high melting
solids which can be purified by recrystallization from toluene, benzene, ethanol, DMF etc. The UV spectrum of 76a shows bands at 242 (4.46), 248 (4.44), and 280 nm (3.58) (in H$_2$O) $^{75}$. The IR spectra show two C=O-bands which are generally in the region of 1650-1655 and 1680-1690 cm$^{-1}$; the average integrated intensities are in the same range as those determined for sydnones and isosydnones and are much higher than those observed for covalent carbonyl groups, indicating a highly polar nature of these pseudocarbonyl-groups. On the other hand, the carbonyl stretching frequencies suggest bond orders similar to covalent models. These findings support the charge distribution and bond order calculations $^{17}$. The $^1$H-NMR spectra show the proton at C5 ($R^2=H$) at $\delta = 4.5$ to 5.5 ppm; in CF$_3$COOH this signal is shifted downfield (ca. 1.5-1.8 ppm) with an appreciable broadening (comp. 44a). In CD$_3$OD/CF$_3$COOH this proton is exchanged immediately. The CH$_2$-group in 76a appears at a remarkably low field position ($\delta = 4.2$ ppm in CDCl$_3$).

Saturated analogues of 76 (78) also have been prepared by the trichlorophenyl malonate procedure $^{76}$. These compounds could not be prepared by alkylation of 77; only 0-alkylation occurred $^{76}$. A benzo analogue of 76 (79) is obtained in bright yellow prisms from the corresponding 2-((N-methylamino)-1,3-benothiazole and (chlorocarbonyl)phenylketene in dry THF $^{73}$. The N-CH$_3$ group appeared at $\delta = 3.68$ ppm (CDCl$_3$) in the $^1$H-NMR spectrum (768: $\delta = 3.66$ ppm).

A number of mesoionic thiazolo[3,2-a]pyrimidine-5,7-diones (76) were found to exhibit antibacterial activity against both Gram-negative and Gram-positive organisms $^{77}$. These compounds also have been evaluated as inhibitors of cyclic AMP phosphodiesterase; some substances show theophylline-like activity $^{12}$. Mesoionic imidazo[1,2-a]pyrimidines (80) and 1,2,4-triazolo[1,5-a]pyrimidines (81) were prepared from the corresponding N-substituted aminoheterocycles via the trichlorophenyl malonate procedure $^{78}$ (colorless or slightly colored products). In the carbonyl region, their IR spectra resemble quite closely those of the corresponding mesoionic 4,6-dioxo-1,3-diazines.

---

R = H, Et

77

78

79
Mesoionic 1,3,4-thiadiazolo[3,2-a]pyrimidine-5,7-diones (82) were obtained from 2-sec-amino-1,3,4-thiadiazoles (81) via the trichlorophenyl malonate route. The required thiadiazoles were prepared from the corresponding alkylamines by conversion to alkyl isothiocyanates (Kaluza reaction) which were then treated with hydrazine to give N-alkylthiosemicarbazides; treatment of these compounds with triethyl orthoformate under acid catalysis gave the desired thiadiazoles in high yields.

Whereas compounds of type 82 (mesoionic purin-2-one analogues, Scheme 13) are unknown, derivatives of type 83 (mesoionic hypoxanthines) have been described. The parent system can exist in various tautomeric forms (e.g. 84, 85); 6-oxopurine (hypo-
xanthine) exists predominantly in the oxo form (84,85)\(^2\) with no indication of 86. Pullman and Pullman\(^3\) used quantum chemical methods for the study of this annular tautomerism; CND0/2 calculations revealed an almost equal energy for 84 and 85. In the crystal state, the N9-H tautomer is present\(^4\); UV comparisons (in H\(_2\)O) on the contrary indicate the N7-H form for hypoxanthine\(^5\).

3-Methylguanine (88), which is available by ring closure of 2,4,5-triamino-3-methyl-6-pyrimidone 87 (as sulfate) with boiling formamide or by hydrolysis of 2-amino-6-chloro-3-methyl-purine (89) with 1N hydrochloric acid\(^6,87\), seemed to be a likely candidate to exist in a mesionic form (88a)\(^6\). Pullman\(^8\) concluded via molecular orbital calculations that 3-methylguanine probably exists as N7-H tautomer; these calculations predicted the mesionic form to be about 50 kcal/mol less stable than any of the usual tautomers. The results of a recent crystal structure determination have clearly shown that 3-methylguanine exists as the N7-H tautomer (2-amino-3,7-dihydro-3-methyl-6H-purine-6-one, 88) proposed by Pullman\(^8\).

True mesionic hypoxanthines have been obtained by Coburn and Carapella\(^9\). Treatment of the previously reported 1,3-dibenzy1hypoxanthinium bromide (90a)\(^1\) and 1,3-dimethyl-8-phenylhypoxanthinium iodide (90b)\(^2\), respectively, as a suspension of the
salt in dry acetonitrile with an excess of a strong base ion-exchange resin at room temperature, yields \(91a, b\), 1,3-Diethyl-8-phenylhypoxanthinium iodide (90c) - prepared from 8-phenylhypoxanthine and ethyl iodide - results on treatment with an aqueous solution of 5% sodium bicarbonate (to \(p_H 7\)), in the precipitation of 91c. The mesoionic compounds 91a-c are obtained as white crystals stable to heat and light in air. Some spectroscopic properties are summarized in Table 4.

\[90a-c \rightarrow 91a-c\]

**TABLE 4:** Spectroscopic Properties of Mesoionic 1,3-Dialkylhypoxanthines (91a-c).

\(^a\) Solvent shifts in acetonitrile: +6, +6, and +7 nm, resp.; \(^b\) Variable electronegativity PPP-SCF-CI\(^17\)\(^b\) (10 singly excited configurations); \(^c\) Adjusted.

Recent investigations in the 8-azapurine series have shown\(^93\) that the 3-alkyl derivatives exist in the neutral form (e.g. 92); the IR spectrum suggests a strong dipolar...
contribution (92b) to the resonance hybrid. As in the case of 3-methylguanine a mesoionic tautomer (93) does not seem to be present.

4.1.2 Mesionic 4,6-Dioxo-1,3-oxazines

Derivatives of the parent system of this class of compounds (94, 4H-1,3-oxazine-4,6(5H)-dione) have hardly been described up until now95; even quantum chemical calculations are still lacking. It would be of interest to investigate whether 94 (which exists probably as the hydroxy tautomer 95) or simple 2,5-disubstituted derivatives might prefer the mesoionic structure; theoretical work ought to be promising in this respect (compare the 3-methylguanine problem)99.

$$\text{N}$$

94

95

96

In strict analogy with the synthesis of 4,6-dioxo-1,3-diazines, mesoionic 4,6-dioxo-1,3-oxazines (98) have been prepared3,47,49 by the reaction of N-monosubstituted amides (97) with malonyl dichlorides (chlorocarbonylketenes95); the trichlorophenyl malonate procedure had been unsuccessful in these cases. The stability of these compounds depends on the substituents, especially at C2 and C5, e.g. 98a suffers from hydrolysis in moist air. Recrystallization should be carried out with proton free
solvents. The spectra support the formulation as mesoionic compounds. In the IR spectra there are two carbonyl absorptions at approx. 1660 cm\(^{-1}\) ("amide") and 1725-1770 cm\(^{-1}\) ("lactonic" carbonyl); the UV spectra show a long wavelength absorption between 300 and 400 nm which depends considerably on the substituents. In the \(^1\)H-NMR spectra, the signals of C2-CH\(_3\), N-CH\(_3\), and OCH\(_3\) (for \(R^2=(4-OCH_3)C_6H_4\)) are shifted to lower fields compared with 4,6-dioxo-1,3-diazines (Chap. 4.1.1).

Bi- and tricyclic 4,6-dioxo-1,3-oxazines (mesoionic 2,4-dioxo-pyrido[2,1-b]-1,3-oxazines \(99\)\(^3\),\(^4\),\(^7\),\(^9\) and mesoionic 1,3-dioxo-pyran[3,2-a]quinolines \(100\)\(^4\),\(^8\)) have been prepared in the same way; these compounds are considerably more stable against hydrolysis than the monocyclic heterocycles \(98\).

The IR spectra of \(99\) differ somewhat from the monocyclic compounds; both the "lactone" carbonyl and the "amide" absorption occur at lower frequencies (1730-1740, 1630-1635 cm\(^{-1}\))\(^3\). The UV spectra show maxima in the region of 360 nm\(^3\).
4.1.3 Mesoionic 4,6-Dioxo-1,3-thiazines

It is well known that N-unsubstituted thioamides may react with malonic acid derivatives (or malonic acid together with dehydrating agents like PCl₅, PCl₃, and acetic acid anhydride) to give 1,3-thiazinediones (4H,1,3-thiazine-4,6(5H)-diones, 101) [97-101].

Little has been known about tautomeric equilibria [102], but recent investigations (IR, ¹H-NMR, ¹³C-NMR, PPP-MO) show the oxo-hydroxy forms (102 and/or 103) [103, 104] to be present. As in the case of amidines (Chap. 4.1.1) and amides (Chap. 4.1.2), N-monosubstituted thioamides [105, 106] and trisubstituted ureas [106] with carbon suboxide, malonyl dichlorides (chlorocarbonylketenes [95]) and - in certain cases [105] - bis(trichlorophenyl) malonates, yield the expected mesoionic 4,6-dioxo-1,3-thiazines (106).
These compounds are less stable than the corresponding mesoionic 4,6-dioxo-1,3-diazines (Chap. 4.1.1) in the presence of water or alcohol. In some cases they are sol-

Spectroscopic Data of Mesoionic 4,5-Dioxo-1,3-thiazines (106)
(Selected examples and data)

SCHEME 16

volatilically cleaved to give the starting materials. The substituent in position 2 plays an important role both in stabilizing the nucleus and in increasing its basicity ¹⁰⁶. Normally the IR spectra show two carbonyl bands. It is of interest that compounds ¹⁰⁶ which are derived from trisubstituted thioureas (106, R²=NR₂) exhibit only a single carbonyl absorption at 1590–1600 cm⁻¹; the UV spectra are considerably different also (Scheme 16).

Applying the previous mentioned synthesis to cyclic thioamides yields the mesoionic heterocycles (107-109, 111, 114, 116-121). Compound 111 has also been obtained by

![Chemical Structures](image-url)
N-alkylation of 112 with diazomethane. It is interesting to note that in this case only the N-isomer (111) was obtained, whereas 115 reacted with diazomethane to give 114 and an O-methylated isomer. 119 could not be obtained by N-alkylation.

4.1.4 Mesoionic 4,6-Dioxo-1,3-selenazines

Selenium-containing mesoionic heterocycles have been described only recently. The α-seleno acid 122 with acetic anhydride/triethylamine has given the mesoionic 1,3-selenazole-4-one (123) as magenta needles in 80% yield. Reaction of a variety of monoprotonic selenoamide derivatives (124) with 1,2-bielectrophiles as α-bromo-phenylacetic acid chloride also yields this system (125). As a logical extension, replacement of the 1,2-bielectrophile in the reaction with selenoamide derivatives with a 1,3-bielectrophile such as (chlorocarbonyl)phenylketene should provide a synthesis for mesoionic 4,6-dioxo-1,3-selenazines. Indeed, when selenothiocarbamate 126 is mixed with the ketene in anhydrous ether at room temperature, 127 is ob-
tained as orange prisms in 53% yield. The IR spectrum shows bands at 1615 and 1675 cm\(^{-1}\). The compound displays a strong UV absorption at 325 nm (\(\log\varepsilon = 4.02\))^54. The corresponding S-ethyl product was similarly formed. Both products decomposed on attempted recrystallization. They were considerably less stable than their appropriate sulfur analogues. The chemistry of these compounds has apparently not been investigated.

4.1.5 Mesoionic 4,6-Dioxo-1,2,3-triazines

Triazenes carrying a free hydrogen condense as the corresponding alkali salts with alkyl iodide and acetyl chlorides to give N-alkyl and N-acyl derivatives\(^{108}\). \(N,N'\)-Di-substituted triazenes (128) with malonyl dichlorides (chlorocarboxylketenes)\(^{95}\) in ether yield mesoionic 4,6-dioxo-1,2,3-triazines (129)\(^{110}\) as yellow to orange (129a-d) or red (129e)\(^{111}\) crystals.

Whereas generalizations concerning the stability cannot be made at the moment, mesoionic 4,6-dioxo-1,2,3-triazines seem to be less stable than mesoionic 4,6-dioxo-1,3-diazines (Chap. 4.1.1);\(^{129a-c}\) could not be recrystallized and 129b suffers from solvolysis when heated for prolonged times in methanol. (For details on the activities, see Chap. 5.)

The IR spectra show a broad, intensive CO-absorption in the region of 1630-1680 cm\(^{-1}\) with a shoulder at slightly higher wave numbers; UV spectra of these compounds have not as yet been published.
4.1.6 Mesoionic 4,6-Dioxo-1,3,5-triazines

5-Azauracil (130) is the parent system of the mesoionic heterocycles to be discussed in this subsection. IR spectra in dioxane and ethanol indicate the dioxo form; the UV spectrum in water is similar to both the N-alkyl and O-alkyl models and on this account difficult to interpret\textsuperscript{112,113}. There is no indication of a mesoionic form (131)\textsuperscript{114}.

Nevertheless monocyclic mesoionic 4,6-dioxo-1,3,5-triazines (133) are easily prepared by the reaction of \(N,N'\)-disubstituted amidines (132) with phenoxycarbonyl isocyanate\textsuperscript{115} as white crystals with a pronounced susceptibility for hydrolysis. The synthesis obviously proceeds through an intermediate product. As has been reported by

\[
\begin{array}{ccc}
\text{132 a-e} & \xrightarrow{\text{PhOCNCO}} & \text{133 a-e} \\
\end{array}
\]

Kappe and coworkers\textsuperscript{116}, the amidine 134 reacts with ethoxycarbonyl isocyanate at room temperature to produce the allophanic ester 135, which on heating in cyclohexane yields 136. The monocyclic mesionic 4,6-dioxo-1,3,5-triazines show two C=O bands in their IR spectra (1680-1690 and 1725-1730 \text{cm}^{-1}); the UV spectrum of 135\textsubscript{a} exhibits a short wavelength absorption at 230 nm (1g\textsubscript{e} = 3.993 in THF). In a strictly comparable reaction of N,N'-diphenylacetamide (137) with phenoxy carbonyl isothiocyanate and phenoxythiocarbonyl isothiocyanate (generated in situ from phenoxythiocarbonyl chloride and lead thiocyanate) in refluxing toluene, the monothiolo (137) and dithiolo compound (139) are respectively yielded\textsuperscript{115}.

In general compounds of type 133, 136 appear to be somewhat less stable than their 5-deaza analogues (Chap. 4.1.1); quantitative experiments, however, are still lacking. Bicyclic derivatives of the mesionic 4,6-dioxo-1,3,5-triazine system are known also. 2-Amino-substituted 1,3-thiazoles (140) react with phenoxy carbonyl isocyanate to produce 141; with ethoxycarbonyl isocyanate, only acylation of the aminothiazoles is observed\textsuperscript{117}. Ethoxycarbonyl isothiocyanate and phenoxy carbonyl isothiocyanate exhibit a remarkable difference in their reactivity towards 140\textsubscript{a},\textsubscript{b}; whereas the former\textsuperscript{118} yields 142\textsubscript{a},\textsubscript{b}, the latter (generated in situ from phenylchloroformate and potassium thiocyanate in anhydrous ethyl acetate) leads to 143\textsubscript{a},\textsubscript{b}\textsuperscript{117}. In a similar fashion, 144 and 146 are obtained from 2-ethylamino-1,3,4-thiadiazole (145)\textsuperscript{117}. As in the case of amidines (see above), N-substituted 2-aminopyridines (147) react with ethoxycarbonyl isocyanate in the first step to give allophanic esters (148); the mesionic 2,4-dioxo-pyrido[1,2-a]-s-triazines (149) are obtained by refluxing
a: Generated in situ; b: No reaction with ethoxycarbonylisothiocyanate.

**a:** H₂O; **b:** CF₃COOH; **c:** Should probably be 8.26 (W.F.);
**d:** CDCl₃; **e:** Shoulder; **f:** DMSO-d₆; **g:** CH₃OH.

**These intermediates in xylene**¹¹⁶. Compounds of type 150 have been prepared from appropriate N-substituted aminopyridazines and phenoxy carbonyl isocyanate in dry acetonitrile⁷²ᵃ. Their in vitro antimicrobial activity has been tested.
In a recent publication, the preparation of 153a,b and 155a,b as depicted above has been described. Whereas the ring closure of 152a to 153a proceeds as usual, the transformation 154 → 155 is effected by a catalytic amount of trifluoroacetic acid. In contrast to the alkylation of "malonyl-α-aminopyridine" and related compounds (Chap. 4.1.1), 156 with benzyl chloride affords only a N3-substituted derivative (157).

\]

The mesoionic bicyclic dioxo-1,3,5-triazines show two carbonyl bands in their IR spectra. The assignment is made possible by comparison with the oxo-thiono compounds 142, 143, and 146. As can be seen from the data of 141a, 142a, and 143a in Scheme 17, both the position and the intensity of the long-wave UV band depends greatly on the substitution of an oxo- by a thiono group; this seems not to be the case for 144 and 146.

4.1.7 Mesoionic 4,6-Dioxo-1,3,5-thiadiazines
As early as 1972, the reaction of cyclic thioureas (158) with chlorocarbonyl isocyanate has been described. In the first step of this reaction, salt-like adducts (159) are obtained which on deprotonation yield the mesoionic compounds 160; 160a could also be obtained directly from 158a with phenoxy carbonyl isocyanate in refluxing toluene. The introduction of one carbon unit in 161 in the presence of an amine also yields this new mesoionic system.

The photoelectron spectra of 160 show two signals in an intensity ratio of 2:1. Other spectral data have not been given.
The introduction of heteroatoms (N-,O,S) in the positions 4 and 5, as well as 7 and 8, of the m-quinodimethane dianion (1) leads to a new mesoionic 1,3-dipolar system.

4.2 1,3 - DIPOLAR SYSTEMS

4.2.1 Mesoionic 3,5-Dioxo-1,2,4-triazines
(A, Chap. 2) of which examples seem to be unknown. Further introduction of a nitrogen atom in position 2 creates a class of compounds (e.g. 162) which have recently come to light. The basis system, 6-azauracil (163), exists in the dioxo form (163a)\(^{120,121}\) with no indication of the mesoionic tautomer (163b)\(^{122,123}\). Alkylations of 6-azauracil with alkyl iodides, dialkyl sulfates or benzyl chloride in aqueous alkali afford the 2- and 4-monoalkyl or 2,4-dialkyl derivatives, depending on the reaction conditions. The course of the reaction between 162 and dimethyl sulfate is different when alkali is absent; in this case, the mesoionic six-membered heterocycle 164 is obtained in about 40% yield\(^{127}\). The structure was confirmed by \(^1H\)-NMR (\(\delta\) (CH\(_3\)) = 3.92, \(\delta\) (H6) = 8.03 ppm (166: \(\delta\) (CH\(_3\)) = 3.45, \(\delta\) (H6) = 7.36 ppm (in DMSO-d\(_6\))) and IR. The compound 164 is hydrogenated over Adams catalyst to afford 165 in 83% yield.

Quite recently a compound has been described which may be a benz analogue of 162. The pyrylium tetrafluoroborate 167 reacts smoothly with semicarbazide to form the ureido-derivative 168 which on treatment with potassium carbonate in dimethoxyethane cyclized to 169 (mp. \(> 325^\circ\)C (EtOH); \(\nu\)\(\)\(\text{max}\) (CHBr\(_3\)) : 1710, 1630, 1610 cm\(^{-1}\)). Whether this product should be formulated as 162 or as a benz analogue of 162 (170) is open to question\(^{128}\).

No further compounds of type A (Chap. 2) have apparently been described.
4.2.2 Mesoionic 3,5-Dioxo-1,4-diazines

Aziridines may undergo thermally or photochemically induced ring opening reactions to azomethine ylides\textsuperscript{129}, controlled stereospecifically as predicted by the Woodward-Hoffmann rules. In an extension of this work, photolyses of 171a\textsuperscript{130} and 171b\textsuperscript{131} in the presence of DMAD\textsuperscript{29} yield adducts (173a, b)\textsuperscript{132} which probably result from a 1,3-

\[
\begin{align*}
\text{171a, b} & \quad \text{hv} \quad \text{172a, b} \quad \text{DMAD} \quad \text{173a, b}
\end{align*}
\]

\( \alpha: R^1 = \text{PhCH}_2; \quad R^2 = (4-OCH}_3\text{C}_6\text{H}_4 \)

\( \beta: R^1 = (4-OCH}_3\text{C}_6\text{H}_4; \quad R^2 = \text{CH}_3 \)
The dehydrogenation of 1,4-disubstituted piperazinediones (174a,b) with an excess of p-chloranil yields products (176a,b) which have been suggested to result from mesoionic 3,5-dioxo-1,4-diazines (175a,b) as intermediates. Both 172 and 175 can be considered as azomethine ylides or mesoronic six-membered heterocycle of type C (Chap. 2). Whereas 172 and 175 have neither been proved nor isolated, M. Sorm and coworkers have succeeded in preparing stable compounds of this type. In a peculiar reaction, 174a on treatment with either benzenesulfonyl chloride/pyridine or benzenesulfonyl chloride, affords the mesoionic compound 177 as yellow needles which yields of 28% and 9%, respectively. Activated Al reverts 177 back to 174a. The IR spectrum of 177 exhibits two bands in the carbonyl region (1640, 1690 cm\(^{-1}\)); the UV spectrum shows an absorption at 438 nm of medium intensity (log \(\varepsilon\) = 3.17). With maleic anhydride (benzene, reflux) and formaldehyde (THF, room temperature), cycloadducts (178, 179) are obtained; these reactions confirm the structure of 177. Nevertheless an X-ray structure determination is urgently desired.
5. REACTIONS

In this chapter, only reactions of mesoionic six-membered heterocycles of type B (Chap. 2) will be dealt with.

5.1 REACTIONS WITH NUCLEOPHILES

Both mono- and polycyclic mesoionic six-membered heterocycles are more or less susceptible to solvolysis whereby the latter compounds are generally more stable than the former. These reactions are strongly accelerated by acids \(^4^9\). A few examples of this reaction type will be given in this subsection.

Mesoionic 4,6-dioxo-1,3-diazines may add water to give a hydrate (180a,c \(^4^4\); further example \(^5^2\)) which may exist in the carbinolamine form (R=Ph) or in the open chain form (R=H). Further hydrolysis leads to a malondiamide (182) \(^3^5\). In this case, replacement of the 2-phenyl substituent in 42 with a hydrogen atom greatly increases the susceptibility of the ring system to hydrolysis.
Analogous reaction products have been observed with 4,6-dioxo-1,3-oxazines (98); reaction with water or sodium hydroxide leads to 183 and 185, possibly with 184 as an intermediate.

4,6-Dioxo-1,3-thiazines (Chap. 4.1.3) are less stable than 4,6-dioxo-1,3-diazines (Chap. 4.1.1); on hydrolysis usually thioamides and malonic acids are obtained. Compound 119 differs somewhat in this respect; hydrolysis in DMSO yields 186. This mode of ring opening is similar to that reported for 160a (to 161; Chap. 4.1.7).

As already mentioned, 4,6-dioxo-1,2,3-triazines (129) may suffer from solvolysis when heated with methanol; on treatment with 2N HCl (reflux) yields benzylmalonic acid.

In alcoholic solution 4,6-dioxo-1,3,5-triazines are slowly cleaved (e.g. 136) to give
allophanic esters (135); this reaction is accelerated by hydrogen chloride. The cleavage proceeds further to give amidine and iminodicarbonic esters. Cleavage of 76a and 141a with amines affords 187 and 188, respectively, with regeneration of the 1,3-thiazole moiety. It has been reported that a 1,3,4-thiadiazole analogue of 76a (82a) reacts 10³ times faster with amines (89). Compound 141a is decomposed readily when heated in aqueous or alcoholic solution (compare the separate reactions of 144 with ethylamine and water).

5.2 ALKYLATIONS AT THE EXOCYCLIC HETEROATOMS

There seems to be only one report concerning the alkylation of mesoionic six-membered heterocycles of type B (Chap. 2) at the heteroatoms 7 or 8 (94). Compound 57 on
treatment with methyl iodide was found to yield 189. This type of reaction has been investigated extensively in the series of five-membered mesoionic heterocycles; it offers an advantage for introducing carbanionic stabilizing groups other than oxygen or sulfur 1,136.

### 5.3 REACTIONS WITH ELECTROPHILES

Mesoionic six-membered heterocycles of type B (Chap. 2) are amenable to electrophilic substitution reactions provided that they carry a methine group between the carbonyl groups. So far only reactions of **bicyclic** mesoionic 4,6-dioxo-1,3-diazines have been reported 68a. "Malonyl-α-aminopyridine" (60) reacts with DMF/COCl₂ to produce 23% C-formylated product (191, besides 8.3% 190), whereas with DMF/POCl₃, only 190 is obtained. Compound 76a serves as starting material for C-substituted derivatives.
which would be difficult to obtain on other routes. The versatility of these transformations is promising with respect to the preparation of other mesoionic six-membered heterocycles.

In an attempt to cycloadd (Chap. 5.4) TCNE and ethyl azodicarboxylate to "ene-type" reaction products, [(195,196)] have been isolated. Isocyanic acid adds yielding 197 (however, compare the reaction of the 5-substituted 39b with the same reagent, Chap. 5.4.1)37. In a similar manner, 108a reacts with DMAD yielding 198, probably via 198 followed by a 1,4-dipolar cycloaddition (Chap. 5.4) with subsequent loss of COS. A similar reaction type has been encountered in heating a 4,6-dioxo-1,3,5-triazene with DMAD. 

[Diagrams of structures 62a, 195, 196, 42a, 197, 108a, 198, 199]
5.4 CYCLOADDITION REACTIONS

5.4.1 With 2π Components

Mesoionic six-membered heterocycles of type B (Chap. 2) - whether they are mono- or polycyclic - may be envisaged as 1,4-dipolar systems (Scheme 3). As expected for these compounds, the symmetry of the highest occupied molecular orbital (HOMO) and

![HOMO and LUMO](image)

Symmetry of HOMO and LUMO of Mesoionic Six-Membered Heterocycles of Type B (Chap. 2).

Mesoionic 4,6-dioxo-1,3-diazine as representative example (HMO data, parameters: Chap. 3).

**SCHEME 18**

lowest unoccupied molecular orbital (LUMO) (Scheme 18) predicts them to be suitable candidates for cycloaddition reactions with 2π-components. This presumption has been verified in a great number of cases. Representative examples will be given in this chapter.

Mesoionic 4,6-dioxo-1,3-diazines have been shown to react with DMAD producing 2-pyridones (201); the primary [2+4]cycloadduct (200) has been isolated as intermediate. Whereas diethylamino-1-propine, N,N-dimethylamino-phenylacetylene, ethyl propiolate as well as methyl malonate failed to give well defined products,

![Reaction Diagram](image)

a: benzene, 24 h reflux; 94 %
b: 20 min. above mp. (188-189°C)
maleic anhydride\textsuperscript{137a,b} and maleic imides\textsuperscript{15b} add to mesoionic 1,3-diazines yielding 202. The reaction with TCNE gives the cycloadducts 203\textsuperscript{45b}.

\[

\text{d} & \text{Ph} & \text{PhCH}_2
\end{array}
\]

\[X = \text{O, N-Ar}\]

Mesoionic 4,6-dioxo-1,3-diazines such as 39\textsubscript{b,e,g} (and others) react with benzyne (204), prepared from benzenediazonium-2-carboxylate, yielding below 40^\circ\text{C} the primary cycloadducts 205, which can be isolated. At higher temperature the isoquinoline-3-ones (206) are formed under the loss of phenyl isocyanate\textsuperscript{137c}. Compound 39\textsubscript{b} gives with an excess of 204 the adduct 207, which is converted upon heating into the anthracene derivative 208.

\[
\begin{array}{ccc}
\text{39\textsubscript{b,e,g}} & \text{204} & \text{205\textsubscript{b,e,g}} \\
\hline
\text{39, 205, 206} & R^1 & R^2 \\

\text{c} & \text{CH}_3 & \text{PhCH}_2 \\
\text{d} & \text{Ph} & \text{Et}
\end{array}
\]
The addition of isocyanic acid, prepared by the thermolysis of isocyanuric acid or azodicarboxamide, to 39b yields, possibly via the bridged adduct 209 and subsequent loss of phenyl isocyanate, the 6-hydroxy-4-pyrimidone 14b.

Bicyclic mesoionic compounds (e.g., 39b, 76a) add DMAD to produce fused pyridines (210, 211) which might otherwise be difficult to obtain.

---

52a + DMAD (xylene, 24 h reflux 60%) → 210
As has been mentioned above (Chap. 4.1.1) both mono- and bicyclic 4,6-dioxo-1,3-oxazines may react with heterocumulenes (aryl isocyanates, aryl isothiocyanates) to yield the corresponding 4,6-dioxo-1,3-diazenes (or the oxo-thiono analogues)\(^3,47-49\). Compound \(99c\) as well as \(108c\) add DMAD to give the fused \(\alpha\)-pyridone \(212\), albeit in low yield\(^46,49\).

Mesoionic 4,6-dioxo-1,3-thiazines react with aryl isocyanates with the elimination of COS to produce the corresponding mesoionic 4,6-dioxo-1,3-diazenes (Chap. 4.1.1)\(^46\); this transformation has been proven to be a convenient way of synthesizing these compounds, especially in cases where thioamides and aryl isocyanates are readily available. No cycloadducts have been obtained with a variety of acetylenic and olefinic dipolarophiles; conversion into \(4\)-quinolones has been the preferred pathway (Chap. 5.5)\(^106\). The mesoionic 4,6-dioxo-1,3-thiazine \(106a\), however seems to be an
exception. The main product (214) results from a rearrangement of 106a (Chap. 5.5), whereas thiophene 213 is probably formed via an [2+4]-intermediate. An interesting case of regioselectivity is encountered in the reaction of 121a and ethyl propiolate. Only one isomer (215) has been isolated from the reaction mixture.

Both 4,6-dioxo-1,2,3-triazines and 4,6-dioxo-1,3,5-triazines (Chap. 4.1.5, 4.1.6) do not seem to undergo cycloaddition reactions.110,115

5.4.2 With o-Quinonoid Compounds

Certain classes of five-membered mesoionic heterocycles of type 1 react remarkably smoothly with o-quinonoid compounds (o-quinones, o-benzoquinone-dimines) yielding mainly 1:1 adducts of type 216 (formally derived from a valence tautomeric ketene form of the mesoion) and 217.139-141 In an obvious extension of this program, the reactions of both mesoionic 4,6-dioxo-1,3-diazines (Chap. 4.1.1) and 4,6-dioxo-1,3-oxazines (Chap. 4.1.2) with o-quinones have been investigated.
Mesoionic 4,6-dioxo-1,3-diazenes (e.g. 39k) react with tetrachloro-o-benzoquinone (218) to give a compound (219) which can be considered as an adduct of 218 with an open chain ketene tautomer of 39k (220). These tautomers are not involved in this cycloaddition, however, but may be important intermediates in rearrangement reactions (Chap. 5.5). Mesoionic 4,6-dioxo-1,3-diazenes (e.g. 98b) react quite differently. CO$_2$ is evolved with both with o-quinones and with 9,10-phenanthrenequinone; this occurs even at room temperature. The products obtained (e.g. 222) can be rationalized by a primary [4+4] cycloaddition (to 221) with subsequent ring closure.
opening, loss of CO₂, and rearrangement. This sequence can also be formulated as a concerted reaction. The extension of these investigations to o-benzoquinone-dilimines is under way.¹⁴³

5.5 REARRANGEMENTS

Heating of the bicyclic mesoionic 1,3-diazine 62d to about 250°C leads to the neutral benzyl ether 61d in poor yield. (This reaction is in contrast to the conversion of methyl ethers to mesolons; compare 31–32³⁰, or 35–36³⁵, Chap. 4.1) On the other hand, heating of the monocyclic mesoionic 4,6-dioxo-1,3-diazine 223 gives a N→C

![diagram]

migration of the benzyl group yielding the 5,5-dibenzyl-4,6-dioxo-tetrahydropyrimidine 224.¹⁶⁷ A radical mechanism is suggested for both cases, because dibenzyl and "tribenzyl" are isolated as side products.¹⁴⁴

Malonyl heterocycles, such as 5-aryl-4-hydroxy-2-pyrones and benzocoumarins 225 react at higher temperatures via ketenes (226) to thermodynamically more stable carbocyclic compounds 227.¹⁴⁵

It is therefore not surprising that mesoionic N-aryl-2,4-dioxo-1,3-diazines rearrange to 2-quinolones¹⁴⁶. Thus the bicyclic mesoions 41 react at 260–300°C via the ketene...
Intermediate 228 to give the quinolones 229 in good yields. The monocyclic mesoions 39 react in an analogous way (with ketenes, however, the primary products (230) are stabilized by two consecutive reactions leading via 231 to the formation of 232). The mesoions 234 (obtained from 2-aryl aminoquinolines and bis(2,4,6-trichlorophenyl) malonates or 100 and aryl isocyanates) react in 2,4,6-trichlorophenol to yield compound 233; on the other hand, if heated in a high boiling solvent, such as diphenyl ether, the 4-hydroxy-quinolones 235 are formed 148.
Another type of rearrangement for N-aryl-4,6-dioxo-1,3-diazines (39a,b)\textsuperscript{41} and 1,3-thiazines \textsuperscript{106,106}, leading in both cases to the same 4-quinolones, was published independently by two research groups in 1975. Thus the pyrimidines \textsuperscript{29} react in 2,4,6-trichlorophenol at 200°C under loss of phenyl isocyanate to yield the 4-quinolones 236, whereas the 1,3-thiazines \textsuperscript{106} are losing carbon oxysulfide in boiling benzene without catalysts. The mechanism of both reactions can be rationalized by bond formation between C2 and C5 (237), (simultaneous?) loss of X=C=O (238), with subsequent ring opening to the ketene 239 and ring closure to 236. The role of the solvent (trichlorophenol) in the reaction of the 1,3-diazine 29 is not yet clearly understood (compare the rearrangement of 29 to 232 without solvent above 260°C).
The thermolysis of the mesoionic 2,4-dioxo-1,3-oxazine 240 in trichlorophenol at 200°C yields the 2-quinolone 241, obviously by a similar pathway as described for the conversion of 39b to 231. The expected 4-quinolone (236) is formed in a low yield (1.6%) only, and at the present time there is no explanation for this different behavior of the oxazine 240 from the reaction of the thiazines 106.

An unexpected reaction occurs if the mesoionic 2,6-dioxo-1,2,3-triazine 129a is heated in boiling xylene, yielding the bisazetidine 243, azobenzene and nitrogen 110. Most probably the reaction is initiated by a dimerisation step 150.

6. CONCLUSIONS

Meta-quinodimethane dianion (1) may be considered as a basis system for three types of mesoionic six-membered heterocycles (A, B, C, Scheme 1). Following the ingenious interpretation of Katritzky and Waring concerning the structure of "malonyl-α-aminopyridine", a great number of compounds of type B have come to light. Besides being interesting in their own right, they may serve as source of new heterocyclic systems, both mesoionic and covalent. Mesoions also remain a challenge for crystallographers and theoreticians in exploring the sometimes peculiar bond and electronic properties of these compounds.
ACKNOWLEDGEMENT

Our own investigations have been generously supported by the Deutsche Forschungsgemeinschaft, the Fonds der Chemischen Industrie (W.F.), and the Fonds zur Förderung der wissenschaftlichen Forschung in Österreich (Th.K.). We would like to express our gratitude to these institutions.
