Abstract – The synthesis and reactions of 2-azabicyclo[2.2.0]hex-5-enes and 2-azabicyclo[2.2.0]hexanes are reviewed.

CONTENTS

INTRODUCTION

I. SYNTHESIS OF 2-AZABICYCLO[2.2.0]HEX-5-ENES
A. Synthesis of 2-azabicyclo[2.2.0]hex-5-enes via electrocyclic ring closure.

II. SYNTHESIS OF 2-AZABICYCLO[2.2.0]HEXANES
B. Synthesis of 2-azabicyclo[2.2.0]hexanes via additions to the 5,6-alkene of 2-azabicyclo-
   [2.2.0]hex-5-enes.
   1. Hydrogenation.
   2. Reductive arylation.
   3. Cycloaddition reactions.
      b. [2+1] Cycloaddition reactions.
   4. Oxidative hydroboration.
   5. Halogen and pseudohalogen additions.
      a. Addition of succinimide-N-sulfenyl chloride.
      b. Addition of IX (X = OH, OAc, F)
      c. Addition of phenylselenium bromide.

III. ADDITION/REARRANGEMENT REACTIONS OF 2-AZABICYCLO[2.2.0]HEX-5-ENES
A. Addition of bromine.
B. Addition of BrOH.

IV. CLEAVAGE REACTIONS OF 2-AZABICYCLO[2.2.0]HEX-5-ENES
A. Olefin cleavage of 2-azabicyclo[2.2.0]hex-5-ene.
B. Allylic cleavage of 2-azabicyclo[2.2.0]hex-5-ene.
   1. Cleavage with HCl.
   2. Cleavage with chloronium ion.

This paper is dedicated to Dr. Pierre Potier on the occasion of his 70th birthday.
3. Cleavage with Selectfluor
4. Cleavage with trimethylsilyl iodide
5. Cleavage and regiospecific two-atom insertions with chlorosulfonyl isocyanate.

V. REACTIONS OF 2-AZABICYCLO[2.2.0]HEXANES

A. Azetidine ring cleavage
1. Cleavage with HBr
2. Cleavage with trimethylsilyl iodide

B. Rearrangement of 6-exo-X isomers of N-alkoxycarbonyl-2-azabicyclo[2.2.0]hexanes.
1. Rearrangement of 6-exo-halides
2. Rearrangement of 6-exo-alcohols

INTRODUCTION

The history of the 2-azabicyclo[2.2.0]hex-5-ene ring system begins with the 1970 report of Wilzbach that the parent 2-azabicyclo[2.2.0]hex-5-ene (3a) was synthesized (mg scale) by irradiation of pyridine (1a) at 2537 Å in aqueous sodium borohydride (Scheme 1). Photolysis of 3,5-lutidine (1b) under the same reaction conditions produced the corresponding 4,6-dimethyl-2-azabicyclo[2.2.0]hex-5-ene (3b). Under these conditions the initially formed Dewar pyridines (2) were reduced to 3a and 3b in unspecified yields.¹

\[ \text{Scheme 1} \]

Soon after in 1972, Fowler reported a more general synthetic route to 2-azabicyclo[2.2.0]hex-5-enes based on electrocyclic ring closure of N-alkoxycarbonyl-1,2-dihydropyridines.² Since then, alternative thermal (1985) and photochemical (1987) cycloaddition routes have been developed. This review will explore the scope and limitations of these synthetic methods and will discuss the synthetic utility of the 2-azabicyclo[2.2.0]hex-5-ene and 2-azabicyclo[2.2.0]hexane ring systems. This review will not discuss synthesis or reactions of 2-azabicyclo[2.2.0]hex-5-en-3-ones. A recent overview of the photochemical conversion of 2-pyridones (4) to bicyclo[2.2.0]hexane lactams (5) (Scheme 2) and their utility in the formation of monocyclic β-lactams has been reported elsewhere.³

\[ \text{Scheme 2} \]
I. SYNTHESIS OF 2-AZABICYCLO[2.2.0]HEX-5-ENES

A. Synthesis of 2-azabicyclo[2.2.0]hex-5-enes via electrocyclic ring closure.

Following Wilzbach’s groundbreaking efforts (Scheme 1), Fowler and coworkers developed an improved synthetic route to the parent 2-azabicyclo[2.2.0]hex-5-ene (3a) from pyridine using an isolated N-acyl-1,2-dihydropyridine (6) as an intermediate (Scheme 3).\(^2\)\(^,\)\(^4\) Irradiation of \(N\)-methoxycarbonyl-1,2-dihydropyridine (6) in acetone could be carried out on a multigram (40 g) scale to give \(N\)-methoxycarbonyl-2-azabicyclo[2.2.0]hex-5-ene (7a) in 50% yield. The presence of the carbamate functional group is necessary for successful ring closure. Reaction with methyllithium and subsequent hydrolysis of the carbamate (7a) gave the parent 3a, although the yields were unspecified. Alternatively, hydrolysis of the carbamate could be accomplished by reaction of 7a with 2M sodium hydroxide in refluxing ethanol for 24 hours.\(^5\)

![Scheme 3](image)

The synthesis of a variety of \(N\)-substituted 2-azabicyclo[2.2.0]hex-5-enes was accomplished by reacting the appropriate alkylating reagent with 3a and diisopropylamine. Compound (3a) was reacted as a tetrahydrofuran distillate from the hydrolysis of carbamate (7a); the yields reported below in Scheme 4 are overall from the carbamate (7a).\(^4\)

![Scheme 4](image)

\(N\)-Methyl-2-azabicyclo[2.2.0]hex-5-ene (7i) was prepared by the LiAlH\(_4\) reduction of the carbamate (7a); the isolated yield was 80%.\(^4\)

![Scheme 5](image)
Expanding on Fowler’s methodology, the irradiation of substituted 1,2-dihydropyridines has provided a variety of \(N\)-alkoxycarbonyl-2-azabicyclo[2.2.0]hex-5-enes. \(N\)-Alkoxycarbonyl substituents are important because they stabilize both the dihydropyridine reactant and the resulting 2-azabicyclo[2.2.0]hex-5-ene, making both structures more resistant to air oxidation than simple \(N\)-alkyl derivatives. For example, amine (7i) has a half-life of 0.77 hours at 125 °C, while carbamate (7a) has a half-life of 1.13 hours at 157 °C.\(^4\) The reaction of alkyl chloroformates with substituted pyridines (8) in the presence of sodium borohydride produced substituted 1,2-dihydropyridines (9), which in turn can be irradiated to produce \(N\)-alkoxycarbonyl-2-azabicyclo[2.2.0]hex-5-enes (10) with substituents at carbons 1, 4, 5, and 6 of the ring (Table 1).

\(^a\) Yield based on 8.

The synthesis of 2-azabicyclo[2.2.0]hex-5-ene (7a) was also accomplished by irradiation of 2-azabicyclo[3.1.0]hex-3-ene (11).\(^{12}\) Irradiation of 11 produced 1,2-dihydropyridine (6) in 30 – 85% yield via the 1-azahexatriene intermediate (12); 12 was confirmed by direct observation when the photoirradiation was conducted in pentane at -40 °C. However, prolonged irradiation of 11 resulted in the formation of 7a (yield unspecified), presumably by photolytic ring closure of 6.
Preparation of 3-endo-substituted N-alkoxycarbonyl-2-azabicyclo[2.2.0]hex-5-enes (14) is accomplished by irradiation of 2-substituted 1,2-dihydropyridines (13). For example, selective 1,2-addition of phenylmagnesium bromide at C2 of pyridine (8a) in the presence of methyl chloroformate provides 1,2-dihydropyridine (13a), which upon irradiation in CH₂Cl₂ affords 3-endo-phenyl-2-azabicyclohexene (14a) by a torquoselective disrotary ring closure. Structures formed by this method are shown in Table 2. Because the 1,2-dihydropyridines (13) are typically unstable to chromatography, the residues formed upon alkyl chloroformate trapping of the addition products of organomagnesium reagents to pyridines were irradiated directly to the ring closure products (14). The substituent R₂ at C3 of the photoproducts (14) has been shown to be endo-oriented, when applicable, based on the large coupling between H₄ and H₃x in the ¹H NMR spectra.¹³⁻¹⁵

a. Yield based on 8.

The preparation of 3-phenyl- and 3,3-di(trifluoromethyl)-2-azabicyclo[2.2.0]hex-5-enes by cycloadditions of N-acylimines and cyclobutadienes has been reported.¹⁷,¹⁸ As shown in Scheme 7, 3-phenyl-2-azabicyclo[2.2.0]hex-5-enes (18 and 19) result from either thermal or acidic isomerization of the corresponding oxaaazabicyclo[4.2.0]hexenes (17) that are formed from a thermal [4+2] cycloaddition of 15 and 16. Isolated yields of 17a-e range from 51 – 70%. Exo by-products (18c) and (18d) were also observed in yields of 7% and 10-24%, respectively. Isomerization of either 17 or 18 produced the thermodynamically more stable endo isomer (19) in yields ranging from 20% to quantitative.
Cycloaddition reactions of 15a and 20a-c produced 2-azabicyclo[2.2.0]hex-5-enes (21a) (64%), (21b) (89%), and (21c) (59%); these reactions are portrayed in Scheme 8. Acid isomerization of 21a and 21c yielded 22a (90%) and 22c (26%); equilibrium conversions between 21b/22b and 21c/22c could be followed by \(^1\)H NMR. Thermolysis of 21b and 21c at 165 °C yielded 23b (58%) and 23c (38%), respectively.\(^{18}\)
II. SYNTHESIS OF 2-AZABICYCLO[2.2.0]HEXANES.

Swindell,\textsuperscript{19} reinvestigating previous work by Schell,\textsuperscript{20} reported that irradiation of vinylogous imides (24) through pyrex optics resulted in the formation of 2-azabicyclo[2.2.0]hexanes (25a) and (25b) as minor photoproducts. The other products have the 2-azabicyclo[2.1.1]hexane skeleton. The structures of products (25a) and (27a) were determined by X-Ray analysis.

Scheme 9

B. Synthesis of 2-azabicyclo[2.2.0]hexanes via additions to the 5,6-alkene of 2-azabicyclo[2.2.0]hex-5-enes.

The olefinic linkage of 2-azabicyclo[2.2.0]hexanes can be functionalized by a variety of methods. In the following sections the regiochemical and stereochemical outcomes of various functionalization methods will be discussed.

1. Hydrogenation.

Treatment of N-benzyloxy carbonyl-2-azabicyclo[2.2.0]hex-5-ene (10b) with H\textsubscript{2} resulted in the reduction of the double bond and removal of the N-benzoxy carbonyl group to provide the parent 2-azabicyclo[2.2.0]hex-5-ane (28) \textit{in situ}. Subsequent reaction with di-\textit{tert}-butyldicarbonate produced \textit{N-tert}-butoxycarbonyl-2-azabicyclo[2.2.0]hex-5-ane (29) in 72% yield based on 10b.\textsuperscript{21}

\begin{align*}
&\text{10b} \\
&\text{H}_2/\text{Pd/C} \\
&\text{28} \\
&\text{(BOC)}_2\text{O} \\
&\text{29}
\end{align*}

Scheme 10

Hydrogenation of \textit{N}-alkoxy carbonyl-2-azabicyclo[2.2.0]hex-5-enes (10h) (Scheme 11) and (14b) (Scheme 12) likewise resulted in the reduction of the double bond.\textsuperscript{10} Hydrogenation of 10b selectively occurred from the \textit{exo} face to afford 5-\textit{endo}-hydroxymethyl-2-azabicyclo[2.2.0]hexane (30). Mitsunobu coupling of the hydroxyl groups of 30 and 32 with 2-chloro-5-hydroxypyridine gave the 5-\textit{endo}-pyridoxymethyl analogues, and the removal of the \textit{N}-methoxy carbonyl group with methyl-lithium/lithium bromide produced the free amines (31) and (33) respectively. Amines (31) and (33)
were evaluated for binding to nicotinic receptors, but both were found to be less effective as nicotine agonists than epibatidine or ABT-594.\textsuperscript{10}

![Scheme 11](image1)

![Scheme 12](image2)

**2. Reductive arylation.**

The double bonds of 2-azabicyclo[2.2.0]hex-5-enes (7a) and also (10a) have been reductively arylated using 3-iodo-6-chloropyridine in the presence of Pd(OAc)$_2$, P(Ph)$_3$, piperidine, DMF, and formic acid to afford a mixture of 5-exo- and 6-exo-aryl isomers (34 and 35, respectively).\textsuperscript{22} The ratio of regioisomers (34) and (35) was temperature dependent and varied somewhat from trial to trial.

![Scheme 13](image3)
Compound (34a) could be epimerized in several steps. NBS bromination gave bromide (36), and subsequent DBU elimination of HBr gave alkene (37). Selective catalytic reduction from the *exo* face of 37 with H₂/PtO₂ produced 5-*endo*-aryl isomer (38) in an overall 20% yield (Scheme 14).

![Scheme 14](image)

Regioisomer (35a) was alternatively epimerized. NBS bromination gave bromide (39), which was reduced stereoselectively with (Me₃Si)₃SiH/AIBN/toluene to give structure (40) (22% yield). This method of epimerization was employed because compound (39) did not undergo elimination of HBr without decomposition (Scheme 15).

![Scheme 15](image)

The N-methoxycarbonyl group of compounds (35a, 38, and 40) was cleaved by reaction with methyl-lithium/lithium bromide ether solution in dry THF to give the corresponding free amine (see Schemes 11 and 12); yields are 44, 85, and 63 %, respectively. These free amines were evaluated for binding to nicotinic receptors, and results corroborated the finding that a bridged ring is crucial for analgesic activity of epibatidine analogues.²²

3. Cycloaddition reactions.

Warrener reported the reaction of 2-azabicyclo[2.2.0]hex-5-enes (7a) and (7i) with 2,5-dimethyl-3,4-diphenylcyclopenta-2,4-dieneone (41) in refluxing benzene to yield cycloadducts (42a) and (42i) (Scheme 16); no yields or stereochemistry were reported.²³ Irradiation of the cycloadducts (dilute solution, CHCl₃, -20 °C, quartz, dry N₂) resulted in decarbonylation to dienes (43a) and (43i), which further fragmented to yield 1,4-dimethyl-2,3-diphenylbenzene (44) and the corresponding Δ²-azetines (45a) and (45i) (Scheme 17); no yield was reported for 45a.
Schem 16

\[ \text{7a } R = \text{COOMe} \]
\[ \text{7i } R = \text{Me} \]

\[ \text{41} \]

\[ \text{42a } R = \text{COOMe} \]
\[ \text{42i } R = \text{Me} \]

Scheme 16

Hydrolysis of cycloadduct (43a) produced the parent 43b, which was subsequently converted to the N-tosyl derivative (43c) by reaction with toluenesulfonyl chloride in pyridine (no yields reported).

\[ \text{43a } R = \text{COOMe} \]
\[ \text{43b } R = \text{H} \]
\[ \text{43c } R = p-\text{MeC}_6\text{H}_4\text{SO}_2 \]

Scheme 17

Irradiation of either 43b or 43c does not produce the corresponding \( \Delta^2 \)-azetines (45); no product information was provided.\textsuperscript{23}

b. [2+1] Cycloaddition reactions.

Tsuchiya and coworkers have reported a series of [2+1] cycloaddition reactions of \( N \)-alkoxycarbonyl-2-azabicyclo[2.2.0]hex-5-enes (7a, 10, and 14) to generate \( N \)-alkoxycarbonyl-3-azatricyclo[4.1.0.0\textsuperscript{2,5}]heptanes (46).\textsuperscript{13,14} 3-Aza-oxatricyclo[4.1.0.0\textsuperscript{2,5}]heptanes were produced by a general procedure of adding a methylene chloride solution of \textit{m}-chloroperbenzoic acid to the
2-azabicyclo[2.2.0]hex-5-enes at room temperature (Table 3). Oxirane compounds (46) in toluene were refluxed for 5–10 hours to give 4,5-dihydro-1,4-oxazepines (47) in yields that ranged from 72–95 \%\textsuperscript{14}.

\end{align*}
\]

Scheme 22
The 3-endo-methyl epoxide (60) afforded solely the rearranged bromohydrin (63). It is proposed that the endo methyl group blocks nucleophilic attack from this face in intermediate (61), and carbamate nitrogen participation facilitates formation of the rearranged product (see Section IIIA and IIIB below).

![Scheme 23](image)

Scheme 23

3,7-Diazatricyclo[4.1.0.0^2,5]heptanes (65) are produced by the addition of ethoxycarbonylnitrene (64) generated from N-ethoxycarbonyl-p-nitrobenzenesulfamide (by treatment with triethylbenzylammonium bromide and sodium bicarbonate) to a methylene chloride solution of the 2-azabicyclo[2.2.0]hex-5-enes at room temperature (Table 4). Aziridine compounds (65) were heated in refluxing xylene solutions for 6–10 hours to produce 4,5-dihydro-1,4-diazepines (66) in yields that ranged from 57–89%.

a. Produced by reaction of N-ethoxycarbonyl-p-nitrobenzenesulfamide, triethylbenzylammonium bromide, and sodium bicarbonate with N-alkoxycarbonyl-2-azabicyclo[2.2.0]hex-5-enes.

Fully unsaturated 1,4-diazepines (69f-g) were synthesized by the same method as described previously for fully unsaturated 1,4-oxazepines (50) (see above). Cleavage of the N-carbonylbenzylxoy group (65 to 67) was successfully accomplished without cleavage of the azetidine benzylic amino bond in compounds (67d-f) (Scheme 24).
Scheme 24

Treatment of carbamate (7a) with diazomethane in the presence of copper(I) chloride gave the 7-methylene compound (70) in 21% yield. On heating in refluxing xylene, compound (70) produced the 2,5-dihydroazepine (71) in 79% yield (Scheme 25).

Scheme 25

4. Oxidative hydroboration.

The addition of borane in THF to alkene (10a) followed by 30% hydrogen peroxide in sodium hydroxide afforded low yields of a mixture of 6-exo-alcohol (54) (9%) and 5-exo-alcohol (72) (5%). The 6-exo-alcohol was independently prepared from epoxide (52) (see above). The structure of the 5-exo-alcohol (72) was partially based upon the coupling of the exo proton H6 with H5endo (J = 5.1 Hz).

Scheme 26

5. Halogen and pseudohalogen additions.

a. Addition of succinimide-N-sulfenyl chloride

Tsuchiya reported the reaction of succinimide-N-sulfenyl chloride (73) with the alkene of (7a) in methylene chloride to give a 6:1 mixture of regioisomers (74) and (75) (Scheme 27). The major isomer was originally assigned as structure (75); however, the stereochemical assignments have been reversed on the basis of 400 MHz 1H NMR spectroscopic evidence (50 °C). There was an absence of
major coupling between H6 and H1 in the major isomer, but coupling ($J = 6.5 \text{ Hz}$) in the minor isomer.\textsuperscript{9,25} Both regioisomers were reduced with lithium aluminum hydride at -75 °C to afford the 7-thia compound (76) in 80% yield; compound (76) was subsequently refluxed in toluene for 6 hours to yield the 4-methoxycarbonyl-4,5-dihydro-1,4-thiazepine (77) in 72% yield.\textsuperscript{9}

\[
\begin{align*}
\text{Scheme 27} \\
R = -N\text{-succinimido}
\end{align*}
\]

b. Addition of IX (X = OH, OAc, F)

The reaction of I$^+$ electrophiles with 2-azabicyclo[2.2.0]hex-5-enes was recently reported by Krow.\textsuperscript{8,26} Reaction of N-iodosuccinimide (NIS) with alkene (10a) in aqueous DMSO afforded only 5-endo-hydroxy-6-exo-iodo-2-azabicyclo[2.2.0]hexane (78a). Similarly, reaction of NIS and alkene (10b) in aqueous THF yielded only the iodo alcohol (76b).

\[
\begin{align*}
\text{Scheme 29} \\
10a \ R = \text{Et} \\
10b \ R = \text{CH}_2\text{Ph} \\
78a \ R = \text{Et} \ (97 \%) \\
78b \ R = \text{CH}_2\text{Ph} \ (91 \%)
\end{align*}
\]

Iodo acetate (79) was the only product isolated from the reaction of alkene (10b) and NIS in buffered acetic acid (Equation 22).\textsuperscript{26}

\[
\begin{align*}
\text{Scheme 30}
\end{align*}
\]
In the aprotic solvent system 8:5 nitromethane:methylene chloride, iodine in the presence of mercuric fluoride reacted with alkenes (10) to afford 6-exo-iodo-5-endo-fluoro addition products (80). The structures were readily assigned on the basis of the absence of coupling between H6n and H1, which places the iodo group exo, and the large coupling ($J = 6.8$ Hz) between H5x and H4, which places the fluoro group endo.

\[
\begin{align*}
\text{COOR} & \xrightarrow{\text{I$_2$/HgF$_2$}} \text{COOR} \\
10a \quad R = \text{Et} & \quad 80a \quad R = \text{Et} (72\%) \\
10b \quad R = \text{CH$_2$Ph} & \quad 80b \quad R = \text{CH$_2$Ph} (68\%)
\end{align*}
\]

Scheme 31

c. Addition of PhSeBr

Reaction of alkene (10b) and phenylselenyl bromide in aprotic methylene chloride gives a 7:1 mixture of selenides (81) and (82); the total yield is 83%. The same reaction performed in the more polar solvent system 8:5 nitromethane:methylene chloride alters the ratio of the regioisomers (81) and (82) to 3:1 with a combined yield of 90%.

\[

& + \quad 82
\end{align*}
\]

Scheme 32

III. ADDITION/REARRANGEMENT REACTIONS OF 2-AZABICYCLO[2.2.0]HEX-5-ENES

A. Addition of bromine

Addition of bromine to 2-azabicyclo[2.2.0]hex-5-enes provides 6-exo-5-endo-dibromo addition products (83) in addition to the rearranged 5-anti-6-anti-dibromo-2-azabicyclo[2.1.1]hexanes (84) (Table 5). The unrearranged dibromides (83) are thought to result from an AdE2 mechanism shown in Scheme 33. The bromonium ion (85) is formed by selective coordination at the exo face; subsequent anti addition of bromide at C5, the position remote from nitrogen, accounts for the observed stereochemistry. The rearrangement products (84) are proposed to result from the conversion of bromonium ion (85) to the aziridinium ion (86) via neighboring-group participation by the nitrogen. Regioselective attack at C1 by bromide would account for the formation of the rearranged azabicyclobutanes (84). It is interesting to note that endo methyl- or phenyl-substitution at C3 on 2-azabicyclo[2.2.0]hex-5-enes (14a,d,e) resulted in exclusive formation of the rearranged dibromides. It is hypothesized that the endo C3 substituents on bromonium ion (85) retard the approach of the bromide nucleophile at C5.
Table 5 – Products formed during reaction of \( N \)-ethoxycarbonyl-2-azabicyclo[2.2.0]hex-5-enes with bromine.\(^a\)

</tbody>
</table>

\( ^a \) See also Scheme 39.

Scheme 33

Addition of bromine to the 5-methyl-2-azabicyclo[2.2.0]hex-5-ene (10e) takes a different course; a mixture of unrearranged dibromide (83c) and bromoalkene (87) is formed (Scheme 34). This difference is believed to result from the formation of the tertiary carbocation (88), from which both observed products can be reasonably derived.\(^6\)
B. Addition of BrOH

Reaction of hypobromous acid with 2-azabicyclo[2.2.0]hex-5-enes affords mixtures of unrearranged (89) and rearranged (90) bromohydrins.7,8 Bromonium ion (85) is again the suspected intermediate in a mechanism similar to the one discussed above for the formation of dibromide compounds (83) and (82) (see Table 6 below).

The 5-methyl-2-azabicyclo[2.2.0]hex-5-ene (10e) again affords a by-product attributed to the formation of carbocation (88). In addition to the trans-bromohydrin (89c), a dibromo alcohol identified as 90 with the aid of NOE experiments is produced in a yield of 19%. Compound (92) is believed to result from the reaction of hypobromous acid with olefin (87). Formation of the primary alcohol by attack of water is at the less substituted primary carbon of the bromonium ion (91), ostensibly for steric reasons (Scheme 35).

Table 6 – Products formed during reaction of N-ethoxycarbonyl-2-azabicyclo[2.2.0]hex-5-enes with hypobromous acid.7

</tbody>
</table>
Unrearranged bromohydrins (89a) and (89b) undergo reductive debromination upon reaction with tributyltin hydride in refluxing benzene to yield the 5-endo-substituted 2-azabicyclo[2.2.0]hexanols (93a) and (93b), respectively.\(^6\)

If a neighboring nucleophilic oxygen atom is present as in 3-hydroxymethyl-2-azabicyclo[2.2.0]hex-5-ene (14b), the initially formed bromonium ion (94) is usually captured by intramolecular attack to give the azatricycle (95).\(^{16}\) Protection of the oxygen of 14b with a bulky and relatively acid-stable TBDMS group resulted in longer reaction times with NBS (69 hours versus 19 hours for 14b), but again only tricycle (93) was isolated in 50% yield.\(^{16}\)
The reaction of nosylate (96) with NBS affords a mixture of tricycle (95) and rearranged bicycle (98) \( \text{via} \) intermediate (97) with a positive charge adjacent to the nosyl group (Scheme 38).\(^\text{16}\) Yields varied according to the solvent employed. In 2:1 DMSO:H\(_2\)O, the reaction afforded 9\% tricycle (95) and 16\% rearranged bicycle (98); in 2:1 THF:H\(_2\)O, the reaction afforded 19\% tricycle (95) and 69\% bicycle (98).

![Scheme 38](image)

The oxygen atom attached to the 6-chloro-3-pyridyl group of olefin (99) exhibits neighboring group participation as well; however, in this case the nucleophile \(X^-\) (bromide or hydroxide) exclusively displaces the cationic pyridoxy group from the primary carbon by \(S_\text{N}2\) substitution. The result is formation of bicycle (101).\(^\text{16}\)

![Scheme 39](image)

### IV. CLEAVAGE REACTIONS OF 2- AZABICYCLO[2.2.0]HEX-5-ENES

#### A. Olefin cleavage of 2-azabicyclo[2.2.0]hex-5-ene.

Arakawa reported the conversion of \(N\)-alkoxycarbonyl-2-azabicyclo[2.2.0]hex-5-enes (7a) and (7h) to the corresponding azetidine-\textit{cis}-2,3-diesters (102a) and (102b) by oxidation with ruthenium tetroxide followed by reaction with diazomethane (Scheme 40).\(^5\) Acidic hydrolysis of diester (102b) resulted in the formation of amino acid (103) in 85\% yield. Acidic hydrolysis of diester (102a) afforded a complicated mixture of products which did not include amino acid (103).

![Scheme 40](image)
B. Allylic cleavage of 2-azabicyclo[2.2.0]hex-5-ene.

1. Cleavage with HCl

Fowler and coworkers reported that reaction of $N$-methoxycarbonyl-2-azabicyclo[2.2.0]hex-5-ene (7a) with HCl in benzene yielded olefin (106); yield of the olefin was not indicated. Reaction is probably initiated by protonation of the nitrogen (Scheme 41).

![Scheme 41]

2. Cleavage with chloronium ion.

Reaction of $N$-chlorosuccinimide (NCS) in aqueous THF with 2-azabicyclo[2.2.0]hex-5-enes (7a) and (10b) results in cleavage of the C1-N bond to afford cyclobuten-3-ols (107). When the alkene (7a) is reacted with an excess of NCS in THF/water and heat is applied, ring-opened hydroxyl aldehyde (108) is obtained.

![Scheme 42]

3. Cleavage with Selectfluor.

The reagent Selectfluor or F-TEDA-BF$_4$ (1-fluoro-4-chloromethyl-1,4-diazeniabicyclo[2.2.0]octane bis(tetrafluoroborate)), a source of positive fluorine, reacts with 2-azabicyclo[2.2.0]hex-5-enes (7a) and (10b) in aqueous acetonitrile to afford the cyclobuten-3-ol (109) (Scheme 43). Ring cleavage at the C1-N bond is proposed to be facilitated by addition of the fluoronium electrophile to the nitrogen rather than the olefin. The reaction mechanism is believed to be the same for the reaction with chloronium ion (see above).

![Scheme 43]
4. Cleavage with trimethylsilyl iodide

Trimethylsilyl iodide (TMSI) was reacted with N-benzyloxycarbonyl-2-azabicyclo[2.2.0]hex-5-ene (10b) in acetonitrile at ambient temperature for 24 hours to yield olefin (111).21 It was proposed that the oxygen atom of the carbamate group undergoes silylation to yield the cation (110), which activates the 2-azabicyclo[2.2.0]hex-5-ene toward ring cleavage.

![Scheme 44](image)

5. Cleavage and regiospecific two-atom insertions with chlorosulfonyl isocyanate.

Chlorosulfonyl isocyanate (CSI) was reacted with N-alkoxycarbonyl-2-azabicyclo[2.2.0]hex-5-enes (10) in methylene chloride either at -30 °C (N-ethoxy substituted) or at ambient temperature (N-benzyloxycarbonyl substituted), and the initial products were reacted with thiophenol or sodium sulfate to remove the chlorosulfonyl group.11 Insertion products (110) were isolated; a product (111) also was afforded in a reaction of 10a. The results are shown in Table 7.

![Table 7](image)

An explanation for the molecular rearrangements leading to cyclobutenes (110) and (111) is shown in Scheme 45, using the parent azabicycle (10a) as an example. Addition of CSI to the nitrogen atom on the exo face affords the zwitterionic species (112), which may ring open to give the cyclobutenylallylic cation (113). Intramolecular ring closure of 113 provides azabicycle (110a) upon reductive workup. Alternatively, if chloride ion is present, intermediate (113) may be trapped to afford the chlorocyclobutene (111) upon reductive workup.
Reaction of CSI and N-benzyloxycarbonyl-2-azabicyclo[2.2.0]hex-5-ene (14d) followed by reductive workup with sodium sulfite yielded the unusual product (117) in 70% yield. It is postulated that the endo phenyl group at C3 in 14d may stabilize positive charge at this position as well, leading to the rearrangement shown in Scheme 46.

**Scheme 46**

**V. REACTIONS OF 2-AZABICYCLO[2.2.0]HEXANES**

**A. Azetidine ring cleavage.**

1. Cleavage with HBr

Reaction of N-methoxycarbonyl-2-azabicyclo[2.2.0]hexane (38) with 30 wt % hydrogen bromide in
acetic acid at ambient temperature afforded cyclobutane (119).\textsuperscript{21} In contrast to the cationic 2-azabicyclo[2.2.0]hex-5-ene intermediates discussed above, formation of an allylic cation intermediate is not possible with this saturated ring system. The ring is therefore believed to be cleaved by nucleophilic attack at the primary carbon, displacing the protonated carbamate nitrogen.

![Scheme 47](image)

2. Cleavage with trimethylsilyl iodide

Krow and coworkers reported the reaction of \(N\)-methoxycarbonyl-2-azabicyclo[2.2.0]hexane (34b) with trimethylsilyl iodide in acetonitrile which produces cyclobutane (121).\textsuperscript{22} As shown above in Scheme 44, it was proposed that the oxygen atom of the carbamate group undergoes silylation to yield the cation (120). The ring is cleaved by nucleophilic attack at the primary carbon, displacing the charged carbamate nitrogen.

![Scheme 48](image)

B. Rearrangement of 6-\(exo\)-X isomers of \(N\)-carboalkoxy-2-azabicyclo[2.2.0]hexanes.

1. Rearrangement of 6-\(exo\)-halides

The stereoselective addition/rearrangement of 6-\(exo\)-iodo- and 6-\(exo\)-bromo-\(N\)-alkoxycarbonyl-2-aza-bicyclo[2.2.0]hexanes (89a, 78b, 80b, 122a and 122b) mediated with silver(I) or mercury(II) salts to produce 5,6-difunctionalized-2-azabicyclo[2.2.1]hexanes (123) containing \(syn\)-hydroxy and \(syn\)-fluoro substituents has been recently reported by Krow.\textsuperscript{24,26} Results as reported are shown in Table 8 below.

Selectfluor also effects the rearrangement of 6-\(exo\)-iodo-\(N\)-carboalkoxy-2-azabicyclo[2.2.0]hexanes (78b, 80b, 122a, 122b, and 124) to produce 5,6-difunctionalized 2-azabicyclo[2.2.1]hexanes (125).\textsuperscript{24} The results are summarized in Table 9. The 6-\(exo\)-bromide (89a) that was rearranged with silver(I) fluoride (see Table 8) did not react with Selectfluor; and the 6-\(exo\)-phenylselenide (81) (see Scheme 32) was unreactive with Selectfluor as well.
Table 8: N-Benzylxoycarbonyl-5,6-difunctionalized-2-azabicyclo[2.2.1]hexanes produced by metal-catalyzed rearrangement of 6-exo-iodo(bromo)-N-benzylxoycarbonyl-2-azabicyclo[2.2.0]hexanes

a. Produced by Selectfluor-mediated rearrangement of 6-exo-iodo-N-benzylxoycarbonyl-2-azabicyclo[2.2.0]hexanes in 1:1 MeCN/H₂O.
2. Rearrangement of 6-<i>exo</i>-alcohols.

Reaction of 6-<i>exo</i>-hydroxy-<i>N</i>-carboalkoxy-2-azabicyclo[2.2.0]hexanes (51<sub>a</sub>, 51<sub>b</sub> and 53) and Deoxo-Fluor [bis(2-methoxyethyl)aminosulfur trifluoride] afforded rearranged 5-<i>anti</i>-fluoro compounds (126) (Table 10).<sup>24</sup> The attempted synthesis of the rearranged 5-<i>anti</i>-fluoro (126<sub>a</sub>) via reaction of alcohol (51<sub>a</sub>) with Selectfluor was unsuccessful; no reaction was observed.
