Abstract – The tetracyclic skeleton of thyrsenols A and B has been assembled, with the construction of ring A by \textit{exo}-selective oxacyclization of an epoxybromohydrin, B ring formation by \textit{exo}-selective oxacyclization of hydroxyepoxide followed by solvolytic ring expansion of a tetrahydrofuran to tetrahydropyran, C ring closure by tungsten-promoted \textit{endo}-selective oxacyclization of a hydroxyalkyne, and D ring preparation by asymmetric dihydroxylation of an epoxyalkene accompanied by \textit{exo}-selective oxacyclization. A modified Stille coupling linked two fragments at C\textsubscript{14}-C\textsubscript{15} to directly provide the tetracyclic dienylether.

INTRODUCTION

Marine polyether triterpenes encompass a large class of natural products arising from oxidative cyclizations of squalenes, exhibiting various arrangements of five, six, and even seven-membered ring ethers.\(^2\) Pharmacologically many of these natural products display antitumor, antiinflammatory, analgesic, antiallergy, and antiviral properties, and have been the subject of numerous biological studies. In particular, thyrsiferol (1, Scheme 1) and especially thyrsiferyl 23-acetate (2) exhibit powerful inhibition of cell growth against the P388 lymphoid cancer cell line,\(^3\) whereas the diastereomeric natural product venustatriol (3) shows activity against vesicular stomatitis virus (VSV) and \textit{Herpes simples} virus type 1 (HSV-1),\(^4\) and the structurally unique dioxepanhydrothyrsiferol (4) bearing two fused seven-membered rings is apparently inactive against several tumor cell lines.\(^5\) Thyrsenols A and B (5, 6) represent more highly oxidized congeners of thyrsiferol, with thyrsenol B displaying much greater cytotoxicity against than P388 cell line (IC\textsubscript{50} = 0.016 \(\mu\)M) vs. thyrsenol A (IC\textsubscript{50} = 0.40 \(\mu\)M).\(^6\)

Dedicated in celebration of the 77th birthday of Prof. Ei-ichi Negishi.
As part of our long-standing interest in the synthesis of marine polycyclic ethers including polyether triterpenes,\textsuperscript{7} we set out to explore the preparation of thyrsiferol or one of its congeners (2 - 6) by regioselective and stereospecific epoxide cyclizations.\textsuperscript{8} The total syntheses of thyrsiferols (1, 2), venustatriol (3), and dioxepandehydrothyrsiferol (4) have been achieved by several different laboratories,\textsuperscript{9-12} but to date synthetic activity directed towards the thyrsenols (5, 6) has not been reported. In considering the synthesis of thyrsenols A and B (5, 6), we proposed that late-stage regio- and enantioselective dihydroxylation of the dideoxydidehydrothyrsenol structure 7 would follow cross-coupling of a tricyclic enol ether derivative 8 with tetrahydrofuranyl-containing 9, with these sectors arising from oxidative cyclization synthetic strategies beginning with farnesol (10) and geraniol (11), respectively (Scheme 2).

RESULTS AND DISCUSSION

Our synthesis began with regioselective preparation of the racemic bromohydrin 13 (Scheme 3) from farnesyl acetate (12) as described in the literature, followed by regioselective and enantioselective epoxidation utilizing the Shi ketone, in which the alkene bearing the allylic acetate substituent was electronically deactivated for electrophilic epoxidation. As the Shi epoxidation required a buffer system with pH 10.5, these basic reaction conditions slowly converted the bromohydrin moiety into the undesired terminal epoxide, which was minimized only by diminishing the reaction time and thus decreasing the conversion of 13 into monoepoxide 14. Although protective groups could be introduced onto the tertiary alcohol of 13, the undesired epoxide formed upon removal of these protective groups, so in the end we judged that our original procedure of acid-catalyzed cyclization with careful control of temperature and conversion provided effective throughput of material into the desired bromotetrahydropyran diastereomer 15 as the result of kinetic resolution of the diastereomers of 14.

![Scheme 3. Synthesis of ring A](image)

The principal challenge in constructing the B ring of thyrsenols was achieving the 6-endo-tet cyclization of an epoxyalcohol instead of the 5-exo-tet cyclization predicted by Baldwin's rules. Instead, we elected to undertake a reaction sequence in which the 5-exo-tet cyclization tetrahydrofuranyl alcohol product would subsequently undergo isomerization to give the ring-expanded tetrahydropyranyl alcohol. The Sharpless asymmetric epoxidation was conducted from the triethylsilyl ether derivative 17, as the reaction rates and yields were diminished when the epoxidation was attempted with the corresponding diol. The triethylsilyl ether 16 was preferred over other silyl ethers for its wider range of pH stability and reduced tendency towards migration (Scheme 4). Upon deprotection of the silyl ether from the epoxidation product 18, the tetrahydrofuranyl diol 19 was selectively produced in excellent yield. As a model system for the ring expansion step, the primary alcohol was regioselectively converted into the acetate ester 20, and then the remaining secondary alcohol was transformed to the chloromesylate 21.
Following optimized conditions developed by the Nakata laboratory, upon heating compound 21 in the presence of water and zinc acetate, ring expansion provided the desired tetrahydropyran as a mixture of acetate 23 and diol 24.\textsuperscript{21,22} As the mechanism for the Nakata rearrangement involved initial generation of epoxonium ion 22 followed by addition of water at the tertiary C10, single inversion of each chiral center at C10 and C11 was anticipated to provide the stereochemistry depicted for compounds 23 and 24.

With the success of the model system, we incorporated the carbon atoms necessary for C-ring synthesis by converting the diol 19 into epoxide 26 (Scheme 5) via intermediacy of the primary tosylate 25,\textsuperscript{23} followed by addition of lithium acetylide to provide compound 27.\textsuperscript{24} At this stage, Nakata rearrangement converted the chloromesylate derivative 28 into the tetrahydropyranyl alcohol 29, albeit in lower yield than we had observed in the model system in which the primary acetate had been present. Nonetheless, basic methanolysis of the trimethylsilyl group revealed the terminal alkyne of 30. The C-ring was then formed by endo-selective alkynol cyclization in the presence of stoichiometric tungsten carbonyl to a cyclic Fischer oxacarbene,\textsuperscript{25} followed by reaction with triethylamine and tributyltin triflate to install the tributyltin substituent in tricyclic compound 31 for subsequent Stille cross-coupling.
Several methods were explored for preparation of the D-ring synthon before we settled on the route depicted (Scheme 6), in which the known epoxytetrahydrofuranyl alcohol 35 was prepared in four steps from geraniol (11)\(^{26}\). Although the literature precedent had shown that asymmetric dihydroxylation\(^{27}\) of the epoxysylate 33 with stirring for three days directly afforded the epoxytetrahydrofuran 35, we obtained better results when the dihydroxylation was quenched after five hours, followed by acid-catalyzed cyclization for complete conversion to the tetrahydrofuranyl diol 34, which was stable to isolation and characterization. In a separate step, basic methanolysis of 34 afforded the epoxide 35 from which the remaining tertiary alcohol was protected as silyl ether 36. Copper-catalyzed addition of 2-methallylmagnesium chloride,\(^{28}\) silylation of the resulting secondary alcohol 37, and ozonolysis afforded the methyl ketone 39,\(^{29}\) which was converted into enol triflate 40 via the kinetic enolate of 39.\(^{30}\)
Stille coupling of the stannyl enol ether 31 and enol triflate 40 proceeded with minimal homodimerization of 31, provided that copper iodide and cesium fluoride additives were present (Scheme 7). As the fluoride salt also partially removed the silyl ethers, the dienyl ether product was best isolated as the diol 7 after complete desilylation with excess tetrabutylammonium fluoride.

Scheme 7. Palladium-catalyzed cross-coupling of ABC and D-ring sectors

At this stage, all that remained was the regioselective dihydroxylation of the C15-alkene of 7. We were optimistic of a favorable outcome due to our precedent of a similarly regioselective dihydroxylation of a dienyl ether in a model system directed towards the branched C-glycoside substructure of altromycin B (41 → 42, Scheme 8). Surprisingly, the attempted dihydroxylation of compound 7 with both AD-mix $\beta$ and $\alpha$ gave no reaction, other than eventual decomposition of the dienyl ether after several days. The reaction of 7 with stoichiometric osmium tetraoxide afforded several very polar compounds, none of which matched the proton NMR spectra of thyrsenols A or B. The reaction of osmium tetraoxide with the acetate derivative 43 provided a mixture of diastereomers exhibiting mass spectra consistent with the tetraol arising from dihydroxylation of both alkenes of 43. It appears that the aryl ring of 41 must have played an activating role in the regioselective dihydroxylation of the 1,1-disubstituted alkene, compared to the corresponding C15 alkene of 7 or 43. Moreover the oxygen substituent at the allylic position of 41 may have deactivated the enol ether to dihydroxylation, whereas dihydroxylation occurred slowly but competitively with both alkenes of 43.
Although the tetracyclic skeleton of the thyrsenols was produced, unfortunately the natural product was not obtained, due to the absence of differential reactivity between the alkenes of dienyl ether 7 in the final dihydroxylation step. However, our work has demonstrated a variety of processes for the construction of cyclic ethers, including diastereoselective epoxyalcohol cyclization to form the A ring, ring expansion of a tetrahydrofuranyl alcohol to the tetrahydropyranyl alcohol isomer in the presence of an alkyne substituent, and the first example of tungsten-promoted alkynol cyclization in the presence of an alkyl bromide.

**EXPERIMENTAL**

\(^{1}\text{H}\) and \(^{13}\text{C}\) NMR spectra were recorded on a VNMR-400 spectrometer (400 MHz for \(^{1}\text{H}\), 100 MHz for \(^{13}\text{C}\)) or an INOVA-600 spectrometer (600 MHz for \(^{1}\text{H}\), 150 MHz for \(^{13}\text{C}\)). NMR spectra were recorded on solutions in deuterated chloroform (CDCl\(_3\)) with residual chloroform (\(\delta 7.27\) ppm for \(^{1}\text{H}\) NMR and \(\delta 77.23\) ppm for \(^{13}\text{C}\) NMR) taken as the internal standard, and were reported in parts per million (ppm). Abbreviations for signal coupling are as follows s, singlet; b, broad; d, doublet; t, triplet; q, quartet; m, multiplet. IR spectra were collected on a Mattson Genesis II FT-IR spectrometer as neat films. Mass spectra (high resolution FAB) were recorded on a VG 70-S Nier Johanson Mass Spectrometer. Analytical thin layer chromatography (TLC) was performed on precoated glass backed plates purchased from Whatman (silica gel 60 F\(_{254}\); 0.25mm thickness). Flash chromatography was carried out with silica gel 60 (230-400 mesh ASTM) from EM Science. All reactions were carried out with anhydrous solvents in oven-dried or flame-dried and argon-charged glassware. All anhydrous solvents were dried over molecular sieves and water content assayed by Karl Fischer titration prior to use. The pH 7 buffer solution used in aqueous workups was prepared by diluting Na\(_2\)HPO\(_4\) (18.9 g, 133 mmol) and KH\(_2\)PO\(_4\) (9.1 g, 67 mmol) with deionized water to a volume of 1L. All reagents were purchased from Sigma-Aldrich or prepared as described in the cited literature.
Bromotetrahydropyranyl silyl ether (16): Chlorotriethylsilane (0.41 mL, 2.4 mmol) was added dropwise to a solution of bromotetrahydropyranyl alcohol 15 (0.619 g, 1.6 mmol) and DMAP (0.0649 g, 0.5 mmol) in pyridine (4 mL). The reaction mixture was stirred overnight, diluted with Et₂O (50 mL) and was washed with pH 7 buffer (50 mL). The aqueous layer was extracted with additional Et₂O (3 x 50 mL). The combined organic layers were dried over MgSO₄, concentrated and purified by silica gel column chromatography eluted with a gradient of 3% Et₃N in hexanes to 9% Et₃N in hexanes yielding the silyl ether 16 (0.688 g, 85%) as a clear oil. Allylic alcohol (17): A solution of DIBAL (1 M in dichloromethane, 2.8 mL, 2.8 mmol) was added slowly to a -78 °C solution of allylic acetate 16 (0.688 g, 1.4 mmol) in dichloromethane (3 mL). The reaction mixture was stirred for 1 h, then allowed to warm to room temperature. After 3 h, sodium sulfate decahydrate was added gradually until a gel formed. The gel was diluted with a saturated aqueous solution of sodium potassium tartrate (10 mL) and additional dichloromethane (10 mL). The aqueous layer was extracted with dichloromethane (2 x 10 mL) and the combined organic layers were dried over MgSO₄. After concentration, the crude product was purified by silica gel column chromatography eluted with Et₂O : hexanes (v/v 2 : 8) resulting in allylic alcohol 17 (0.602 g, 96%) as a clear oil. [α]⁺23 = 23.2 (CH₂Cl₂, c 1.74); IR (neat) 3413, 2955, 2876, 2359, 2092, 1640, 1456, 1372, 1237, 1115, 1011, 733 cm⁻¹; ¹H NMR (400 MHz, CDCl₃) δ 0.61 (q, J = 8.0 Hz, 6H), 0.96 (t, J = 8.0 Hz, 9H), 1.17 (s, 3H), 1.26-1.40 (m, 2H), 1.28 (s, 3H), 1.42 (s, 3H), 1.50 (dt, J = 13.2, 4.4 Hz, 1H), 1.68 (s, 3H), 1.81-1.89 (m, 1H), 1.97-2.04 (m, 1H), 2.08-2.19 (m, 2H), 2.25 (dd, J = 13.2, 3.6 Hz, 1H), 3.25 (dd, J = 7.8, 3.0 Hz), 3.88 (dd, J = 12.6, 3.8 Hz, 1H), 4.17 (d, J = 6.8 Hz, 2H), 5.44 (dt, J = 6.8, 1.2 Hz, 1H); ¹³C NMR (100 MHz, CDCl₃) δ 5.8, 7.3, 16.6, 19.4, 23.8, 28.6, 30.9, 31.3, 37.2, 37.3, 37.5, 39.2, 59.7, 75.3, 76.4, 81.1, 123.2, 140.7; MS(FAB⁺) Calcd. for C₂₁H₄₁O₃Br¹Na¹Siov [(M+Na)+] 471.1901, found 471.1899.

Epoxy alcohol (18): 4Å powdered, activated molecular sieves (0.686 g) were suspended in a solution of allylic alcohol 17 (0.602 g, 1.3 mmol) in dichloromethane (11 mL) with stirring. The suspension was cooled to -20 °C and L-(+)-diethyl tartrate (0.07 mL, 0.41 mmol) followed by Ti(Oi-Pr)₄ (0.09 mL, 0.30 mmol) were added. The pre catalyst mixture was stirred for 30 min. An anhydrous solution of i-t-butyl hydroperoxide (5.5 M in decane, 0.7 mL, 3.9 mmol) was added slowly to the mixture and stirred at -20 °C
for 1 h, then placed in the freezer (-25 °C) overnight. The reaction mixture was filtered through celite to remove the sieves and diluted with additional dichloromethane (50 mL) and an aqueous KOH solution (1.5 M, 50 mL). The biphasic reaction was stirred for 1 h. The aqueous layer was extracted with dichloromethane (2 x 50 mL). The combined organic layers were dried over MgSO₄, concentrated and purified by silica gel column chromatography eluted with Et₂O : hexanes (v/v 1 : 3) producing epoxy alcohol 18 (0.605 g, 97%) as a clear oil.

Alkenyl tetrahydrofuranyl alcohol (37): A solution of 2-methylallylmagnesium chloride (0.5 M in THF, 13 mL, 6.5 mmol) was added dropwise to a -40 °C suspension of CuI (0.184 g, 0.97 mmol) in THF (3 mL) and stirred for 10 min. A solution of epoxytetrahydrofuran 36 (1.03 g, 5.0 mmol) in THF (4 mL) was added to the Grignard solution. The reaction was warmed to 0 °C and stirred for 30 min, then allowed to warm to room temperature. The reaction was stirred for an additional 30 min, then diluted with Et₂O (50 mL) and pH 7 buffer (50 mL). The aqueous layer was extracted with additional Et₂O (2 x 50 mL). The combined organic layers were dried over MgSO₄ and concentrated. The crude product was purified by neutral alumina column chromatography eluted with Et₂O : toluene (v/v 1 : 199) yielding unsaturated alcohol 47 (0.992 g, 79%) as a clear oil. **Methyl ketone (39):** Ozone was bubbled through a -78 °C solution of alkene 38 (1.78 g, 4.6 mmol), pyridine (9 mL), methanol (15 mL), and isopropanol (15 mL) with stirring. The reaction was monitored by TLC. After complete consumption of alkene, dimethyl sulfide (1.4 mL, 19.1 mmol) was added and the solution was warmed to room temperature. The reaction mixture was stirred overnight, then concentrated. The crude product mixture was diluted with Et$_2$O (50 mL), washed with pH 7 buffer (3 x 50 mL), then dried over MgSO$_4$ and concentrated. Trimethylsilyl chloride (1.4 mL, 11.1 mmol) was added dropwise to a solution of the resultant oil and imidazole (1.80 g, 26.4 mmol) in THF (7 mL). The reaction mixture was stirred overnight then concentrated. The yellow oil was dissolved in Et$_2$O (50 mL), washed with pH 7 buffer (3 x 50 mL), dried over MgSO$_4$, and concentrated. **Enol triflate (40):** A solution of KHMDS (0.5 M in toluene, 1.5 mL, 0.75 mmol) was added dropwise to a -78 °C solution of methyl ketone 39 (0.261 g, 0.67 mmol) in THF (7 mL). The enolate solution was stirred for 1 h. A solution of N-phenyl-bis(trifluoromethanesulfonimide) (0.362 g, 1.0 mmol) in THF (2 mL) was added dropwise to the enolate solution. The reaction was stirred at -78 °C for 10 min, then allowed to warm to room temperature. After 1 h the reaction mixture was concentrated, diluted with Et$_2$O (10 mL), washed with pH 7 buffer (2 x 5 mL), and dried over MgSO$_4$. After concentration the crude product was purified by silica gel column chromatography eluted with Et$_3$N : hexanes (v/v 3 : 97) yielding enol triflate 40 (0.304 g, 87%). **Dienyl ether (7):** A solution of enol triflate 40 (39.6 mg, 76 µmol) in DMF (6 mL) was degassed by
three freeze-pump-thaw cycles, and then was transferred to a flask containing α-stannyl dihydropyran 31 (42.1 mg, 65 μmol), tetrakis(triphenylphosphine)palladium(0) (1.8 mg, 1.6 μmol), CuI36 (10.4 mg, 55 μmol), and CsF (0.02 g, 0.13 mmol). The reaction mixture was degassed an additional 2 cycles. The mixture was heated to 50 °C and stirred for 22 h. After cooling, the solution was diluted with EtOAc (20 mL), dichloromethane (20 mL) and water (10 mL) and stirred for an additional 1 h. The biphasic mixture was filtered through celite and diluted with saturated brine (20 mL). The aqueous layer was extracted with a EtOAc : dichloromethane (1 : 1) solution (20 mL x 3). The combined organic layers were dried over MgSO4, concentrated, and purified by silica gel column chromatography eluted with a gradient of Et2O : hexanes (v/v 1:4 to 1:1) resulting in a mixture of monosilyl product and free diol. The mixture was diluted with THF (1 mL) and a solution of tetrabutylammonium fluoride (1 M in THF, 1 mL, 1 mmol) and stirred for 1 h. The crude diol solution was concentrated and purified by silica gel column chromatography eluted with methanol : dichloromethane (v/v 2 : 98) yielding the dienyl ether 7 (23.3 mg, 61%) as a waxy solid. mp 119-122 °C; [α]23D -7 (CH2Cl2, c 0.145); IR (neat) 3435, 2972, 2926, 2852, 1641, 1458, 1377, 1321, 1180, 1122, 1105, 1022, 895 cm-1; 1H NMR (600 MHz, CDCl3) δ 1.11 (s, 3H), 1.13 (s, 6H), 1.22 (s, 6H), 1.28 (s, 3H), 1.41 (s, 3H), 1.50-1.58 (m, 3H), 1.62-1.70 (m, 2H), 1.82-1.89 (m, 3H), 1.93-1.98 (m, 3H), 2.07-2.14 (m, 2H), 2.17-2.28 (m, 3H), 2.32 (bt, J = 1.8 Hz, 1H), 2.50-2.55 (m, 1H), 3.10 (dd, J = 11.4, 1.8 Hz, 1H), 3.36 (dd, J = 10.8, 6.0 Hz, 1H), 3.54 (bd, J = 10.2 Hz, 1H), 3.76 (dd, J = 10.5, 5.7 Hz, 1H), 3.91 (dd, J = 12.6, 4.2 Hz, 1H), 4.92-4.93 (m, 2H), 5.41 (bd, J = 1.2 Hz, 1H); 13C NMR (100 MHz, CDCl3) δ 15.4, 20.2, 23.0, 23.9, 24.1, 24.1, 25.2, 26.8, 28.0, 28.4, 30.1, 31.1, 31.2, 31.4, 36.7, 37.4, 59.2, 70.6, 73.5, 74.6, 75.2, 76.5, 76.7, 86.3, 86.5, 87.9, 96.0, 111.4, 142.8, 149.1; MS(FAB+) Calcd. for C30H50O6Br [(M+H)+] 585.2785, found 585.2783.

REFERENCES AND NOTES
1. Based on the M.S. thesis of Mary A. Smart, Emory University, 2008.

16. Trimethylsilyl, *para*-methoxybenzyl, and tetrahydropyranyl ether protective groups were successfully attached to the tertiary alcohol of 13.

17. This preparation of compound 15 was previously described: F. E. McDonald and X. Wei, *Org. Lett.*, 2002, **4**, 593. If the cyclization/resolution was not completely selective (reaction mixture too warm or reaction time too long) the desired bromotetrahydropyran 15 could be separated from the undesired diastereomer by silica column chromatography (eluent hexane : Et₂O v/v 3:1), although the yield was lower.

22. The mesylate could be used in place of the chloromesylate 21, but the rearrangement transformation then required refluxing in aqueous acetic acid. Sc(OTf)$_3$ was a viable alternative to Zn(OAc)$_2$, although longer reaction times were required.

34. MS(FAB+) Calcd. for C$_{32}$H$_{55}$O$_{11}$\(^{79}\)Br\(^{23}\)Na$_1$ [(M+Na)$^+$] 717.2820, found 717.2807.

35. Tributyltin triflate was freshly prepared by dropwise addition of triflic anhydride (0.03 mL, 0.18 mmol) to neat distibutyltin oxide (0.06 mL, 0.12 mmol). The neat solution was stirred for 1 h, then excess triflic anhydride was removed by vacuum. The white solid was used without purification.

36. Ultrapure CuI was further purified by Soxhlet extraction with THF.
